Push buttons (or other devices) that are provided for the purpose of stopping the engine or sigualling to the engine room from various points about the plant, should be easily and quickly accessible, and should be conspicuously marked so that they can be located instantly. All stop devices should be tested frequently and regularly, to see that they are in good working order; but severe penalties should be imposed for stopping the engine except in time of serious emergency or by express direction of the foreman or some other person in authority, and a notice stating these penalties should be posted in close proximity to every stop-device. In time of emergency the full load should be left on the engine, if possible, because this causes it to stop more quickly. In time of danger workmen often unthinkingly shut down machines that have no direct connection with the emergency and by thus lightening the load cause the engine to run longer.

When jet-condensing engies are used, automatic devices should be installed which will break the vacuum when the water in the condensed reaches a predetermined height. If this is not done, the slowing down ow the air pump, which would occur if the pump is of the attached type, might cause the condenser to become flooded, in which case the water would flow back into the engine cylinders, and the engine would probably be wrecked or badly damaged. Over-speed devices, when used on condensing engines, should be arranged to break the vacuum as well as shut off the steam.

The control lever or wheel which operates the throttle valve is frequently located directly in the plane of the fly-wheel, where the engineer is exposed to the greatest possible danger when he undertakes to stop a racing engine by shutting off the steam by hand. In some cases this cannot well be avoided without a considerable modification in the

design of the engine, but it is often, we think, due to mere thoughtlessness. When the throttle valve is located in a dangerous place we strongly recommend extending the spindle (when this is possible), so that the lever or wheel which operates it can be manipulated from a position of comparative safety.

Special attention and care should be given to the dash-pots of Corliss engines, because if these get out of order the speed of the engines will be irregular. When oiling the valve-gear a little oil should be placed in each dash pot to make sure that the piston of the dash pot fits its cylinder air-tight at all times. If this piston becomes worn so that it is no longer easy to keep it air-tight, repairs should be made at once, and when a new dash pot piston is put in special pains should be taken to see that it neither sticks nor fits too loosely, and to adjust it so that it will operate effectively. The dash pots should have the full amount of drop, and should work in complete harmony with the governor in the control of the engine. Careful attention should also be given to the packing of the stems of the cutoff valves because if the packing is too tight the valves may stick, thereby delaying the cutoff and causing the engine to speed up.

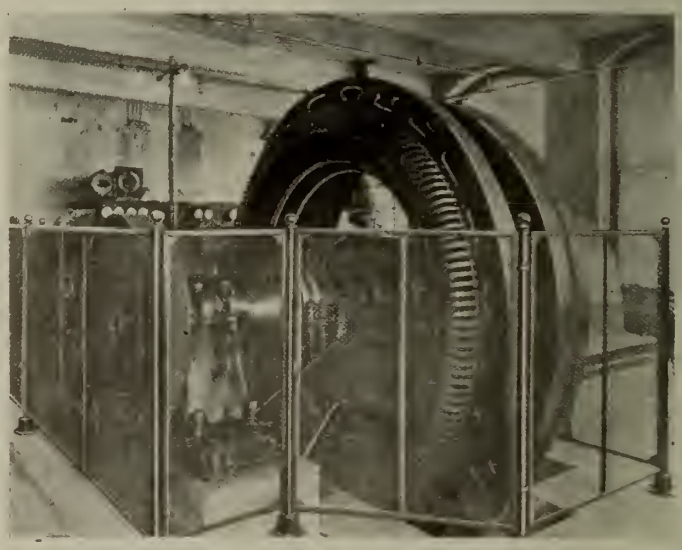
Engine flywheels should be guarded by substantial railings of pipe, angle iron or wood, or by inclosures of some other acceptable kind to prevent persons from coming in contact with them. When railings are used, and the wheel runs in a pit, a toe-board at least six inches high should also be provided, to prevent tools and other objects from falling into the pit. Inclosures may be constructed of solid, perforated, or expanded metal, or of stout and substantial wire netting. Employees should never be permitted to go inside the guard railings, for any purpose whatsoever, while the engine is running, and they should not be allowed to store oil-cans, tools, waste, or other objects inside of these railings or screens, nor to hang clothing upon them.

It is sometimes necessary to turn the flywheel over by means of a Johnson bar or some other hand turning device, and the guard rails or inclosures are often made removable at some convenient point, to permit this work to be done. This is not recommended, however. There should be no door or grate in the inclosure or railing, and any opening that may be provided for inserting and applying the Johnson bar should be limited to the smallest size that will permit the "barring-over" operation to be accomplished. (It is extremely dangerous to turn the wheel over in this way without making sure, beforehand, that the throttle valve is closed tight, and that there is no pressure in the cylinder.)

The suggestions given for flywheel railings apply also to main belts or rope drives. The ladders that are often associated with large engines should have similar railings, and all platforms or footways used in connection with such engines should be provided with standard railings and toe-boards. The same principle also applies to all walks located on or about engines, for the use of oilers and others. Substantial guards or inclosures should be provided for the cranks, cross-heads, connecting rods, and tail rods of engines, and for the ends of the main shaft if they project beyond the bearings.

It is advisable to place a heavy plate barrier guard opposite every cylinder head and close to it, so as to diminish the likelihood of injury to persons in the engine room in case any of the cylinder heads should burst. Guards of this kind should be solidly supported, but should be so arranged that they may be removed by means of a crane when it is necessary to get at the cylinder heads.

When the main driving belt of an engine breaks it is likely to do a great deal of damage, and any person who is struck by it will probably be severely injured. It is, therefore, wise to instal special barrier guards in front of such belts, to prevent property damage, injuries and loss of life in case of an accident of this kind. Barrier guards, to be effective, must be strong and solid and must also be secured in place with the utmost care, so that they will be able to successfully withstand the exceedingly severe shock to which they will be subjected in case the belt is thrown against them at full speed.



GUARD FOR DIRECT CONNECTED GENERATOR.

It should hardly be necessary to refer to the importance of keeping the cylinders of engines free from water, yet piston rods are frequently bent and cylinder heads are often fractured in consequence of neglecting this simple and elementary precaution. The water may back up into the cylinder from the condenser (as already described above) or it may come over with the steam in consequence of foaming or priming in the boilers, or it may accumulate in the cylinder from the condensation of the steam admitted to a cold engine preparatory to starting up, or (as happens all too commonly) its presence may be due to the simple fact that the steam main was not properly drained.

Before starting the engine drain the steam main thoroughly in every part. Then open the drain cocks on all the cylinders (and preferably the indicator cocks also), and if water runs out of the drain cocks wait until it has ceased to flow. Then, leaving the drain cocks still open, start the throttle valve a mere trifle (or, in technical language, "crack" it a little), and allow steam to enter the engine slowly, but without the production of pressure), so that the cylinder will gradually become heated up to the working temperature. This must be done, of course, when the engine is in such a position that at least one of the admission valves is open. If the engine is of the compound or multiple expansion type, all the cylinders should be warmed in the same way by opening the pass-over valves. If the cylinders are provided with steam jackets these should also be filled with steam, as the heating of the cylinder will thereby be greatly facilitated; and in plants in which excessive peak loads may occur, or in which there is likelihood of a heavy call for power on short notice, the jackets should be kept filled with steam at all times, so that the engine may be ready to start without the least delay. Attend carefully to the draining of the steam jackets. Vacuum jackets are now being tried out in connection with reciprocating engines, the principle involved being the same as that upon which the familiar vacuum bottle depends. These vacuum jackets are supposed to diminish the loss of heat by radiation to such an extent that the cylinders remain quite hot for a number of hours after the engine has stopped.

When the cylinders have become thoroughly warmed the engine may be started turning over slowly, but the drain cocks should be left open until all danger of the collection of water in the steam-chest and cylinders is past. Under usual conditions this means that the drains should not be closed until the engine has been running at least five or ten minutes. It is advisable to "fiddle" the engine (or cause it to rock back and forth slightly) before turning it over, if it is of the reversible type, or if, on an en-

gine of the Corliss type, the carrier or reach-rod is detachable from the wrist-plate.

Before removing a cylinder head the workmen should make sure that the throttle and exhaust valves are both closed, and that the drains are open, and they should also try the indicator cocks to prove that no pressure remains in the cylinder.

PIPE RAIL GUARD FOR ENGINE CRANK.

See that all moving parts of the engine are kept thoroughly lubricated, and use the right kind of lubricant in each place. Positive force-feed automatic lubricators are recommended for pins and other similar parts, not only because they insure good lubrication, but also because they are more economical in the end, although they are higher in first cost. All lubricating devices should be examined frequently to see that they are properly adjusted, and that the oil flows freely and in suitable quantity.

All parts of the engine should be kept in good adjustment, and all nuts and keys should be kept tight. If knocks or other unusual or abnormal noises are noted, locate them immediately, ascertain the cause, and apply the proper remedy.

Slippery floors in engine-rooms frequently cause falls, and a slip-proof surface of rubber, or other approved non-slip material, should therefore be provided wherever slipping would be attended by special danger, and (preferably) also on the most frequented parts of the floor.

Employees from other departments of the plant should not be permitted to loiter in engine-rooms, nor even to enter them except as their duties may require them to do so. No person, other than those responsible for the operation of the engines, should be permitted to manipulate any valves, nor even to touch any of the mechanism, nor to approach any moving part, except under the direction and supervision of the chief engineer or of some other person in authority.

If the foregoing suggestions are followed, the number of accidents in engine rooms will certainly be materially reduced.

FUEL SAVED BY SCIENTIFIC FEED-WATER REGULATION

Here are some interesting "before and after" feed-water temperature charts that were sent to us by the Northern Equipment Co., Erie, Pa., manufacturers of the well-known Copes boiler feed regulator.

Fig. 1 shows how the feed-water temperature fluctuated before a regulator was installed. The average temperature by actual measurement and computation was only 177 deg. Fahr.

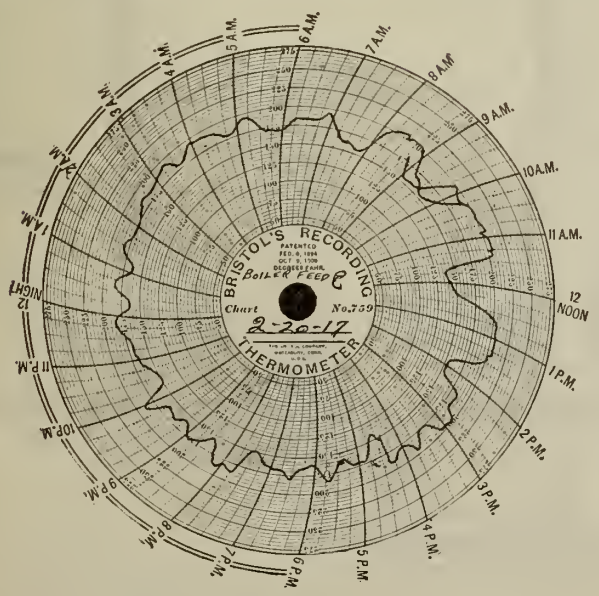
Fig. 2 shows a vast improvement. There is practically no fluctuation in the temperature now that the regulator has been installed, and it is maintained uniformly high, the average temperature being 210 deg. Fahr. A correction in this instance had to be made on account of the recorder reading 12 deg. high.

The average increase in feed-water temperature due to the regulator is therefore (210—177) = 33 deg. Fahr. Since it is customarily reckoned that 11 deg. difference in feed-water temperature is sufficient to save 1 per cent. of the fuel, it is easy to figure that the Copes regulators in this installation are saving 3 per cent. of the annual fuel cost.

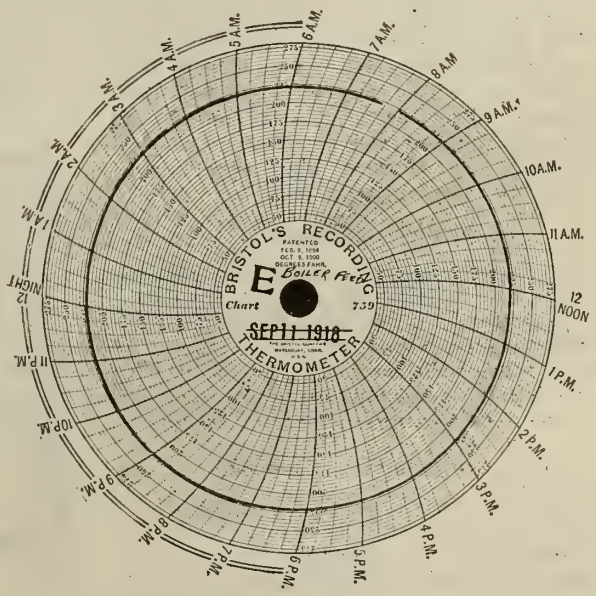
No steam escapes from the heater now that the regulator is installed. Before installation, steam constantly escaped, because with improper regulation the full amount of heat in the exhaust was not utilized. This saving of steam is accomplished by having part of the exhaust steam supplied to the heater controlled by a temperature regulator. The bulb of this regulator is installed in the heater vent and not in the heater outlet as is the usual case. With this arrangement, when any steam begins escaping through the heater vent, the steam supply valve closes quickly.

It has been calculated on the above 3 per cent. basis that these regulators pay for themselves every 15 days, due alone to this saving.

In addition it is pointed out by the manufacturers that with scientific regulation there is an increase in boiler efficiency, an increase in boiler capacity, a saving in wear and tear on pumps, and after relieving the water tender of this undesirable mechanical duty he can be given more pay in an occupation around the plant that requires brain power rather than mere muscle. The modern tendency is toward complete automatic operation everywhere, with human beings serving in a supervisory capacity only. Machinery, machinery, and more machinery, has made the 8-hour day possible, and may eventually reduce it to 6 hours, 4 hours, and even less.



BEFORE FITTING REGULATOR.



AFTER FITTING REGULATOR.

Railway Converter Substations---Part II

The Author Gives Some Useful Information Concerning the Class of Equipment to be Used and Its Arrangement in the Substation Building.

By C. F. LLOYD, Manager Substation Section, Westinghouse Electric and Mfg. Co., Pittsburgh

Regulation and Compounding

Compound wound converters are recommended for railway work, primarily because their regulation is superior and parallel operation is more readily effected than with shunt wound machines. The regulation of a compound converter depends upon three factors, namely: Series Field, Reactance and Ohmic Drop between the source of power and the converter. Compounding is not obtained directly by change in series field as in a D.C. generator, but by changing the machine power factor, which causes any reactance volts behind the machine to be added to or subtracted from the voltage actually applied to the converter collector. The D.C. voltage from no load to full load will be raised, neglecting the drop in the converter due to load, in the same percentage as the voltage is increased at the collector. The A.C. ohmic drop between the source of power and the converter is directly opposed to compounding and should it amount to the same percentage as the percentage increase, then a practically constant voltage will result. The standard method of compounding converters is to adjust the machine shunt field to a valve such that when fully loaded with the series field in circuit, it will be operating at approximately unit power factor. The applied voltage to the collector rings, therefore, at light loads, with the lagging power factor, is reduced as the reactance volts subtract from the generator volts, while at full load unity power factor, the current is in phase with the impressed voltage and the impressed volts are almost equal to the generator volts.

It is practically impossible to correctly determine the values necessary to figure the regulation that will obtain in individual cases, consequently, converter regulation cannot be predicted with any degree of accuracy. Standard Westinghouse Converters are designed with a reasonably heavy series field and their transformers with 15 per cent. inherent reactance, which is the maximum reactance consistent with good practice. Such a combination will give approximately constant voltage from no load to full load, providing the voltage is practically constant at the high tension side of the transformers.

The best results are obtained with slightly dropping voltage characteristics at substations. This means that the converter should be under-compounded in amount depending upon local conditions. Invariably it is good practice to shunt the converter series field to obtain a drop in excess of that which may be due to A.C. line drop. This adjustment allows better distribution of load between substations and, in consequence, better results are obtained when cars become blocked for some abnormal reason.

Parallel Operations

To parallel rotary converters successfully, both the new and the old machines may have to be adjusted to obtain the best results, even though the new equipment is a duplicate of the old. There, however, will be no difficulty in making the proper adjustments, assuming the design of the new apparatus is proper.

Transformers' Standards

Standard transformers for railway converters are listed only in the oil insulated, self-cooled type for converter capacities of 2,000 k.w. and below. Other types and transformers for larger converters are not listed, but can be supplied when required. The following table shows standard listed transformer ratings:

Standard O.I.S.C. Transformer Ratings

Rating. Com. K.W.	Rating. Trans. 1-phase.	Rating. Trans. 3-phase.	V. 2200 Cycle.	V. 6600 Cycle.	V. 11000 Cycle.	V. 13200 Cycle.	V. 16500 Cycle.	V. 22000 Cycle.	V. 33000 Cycle.
300	100	300	60-25	60-25	60-25	60-25	60-25	60-25	60-25
500	167	500	60-25	60-25	60-25	60-25	60-25	60-25	60-25
750	250	750	60	60	60	60	60	60	60
1000	333	...	60-25	60-25	60-25	60-25	60-25	60-25	60-25
1500	500	...	60-25	60-25	60-25	60-25	60-25	60-25	60-25
2000	667	...	60-25	60-25	60-25	60-25	60-25	60-25	60-25

Taps and Terminals

Standard transformers are provided with high tension full capacity taps to take care of a total variation of 10 per cent. in the line voltage. In capacities up to 200 Kva. inclusive, taps are provided for 5 per cent. and 10 per cent. voltage below normal. In capacities above 200 Kva., taps are provided for voltages 2½, 5, 7½ and 10 per cent. below normal. The low tension winding has no taps other than those for obtaining suitable reduced voltage for starting. All low tension leads are brought through the case. All connections available on the high tension are brought up to the terminal board and only such leads as are required for external connections are brought through the case. When different high tension connections are required, they can be made at the terminal board inside the transformer case. There may be isolated cases requiring special high tension tap arrangement with a greater number than standard. This can usually be supplied but costs more and very often makes it impracticable to use 3 phase transformers, due to mechanical reasons. It is usually impracticable to put additional taps on the low tension winding on account of the heavy current and small number of turns.

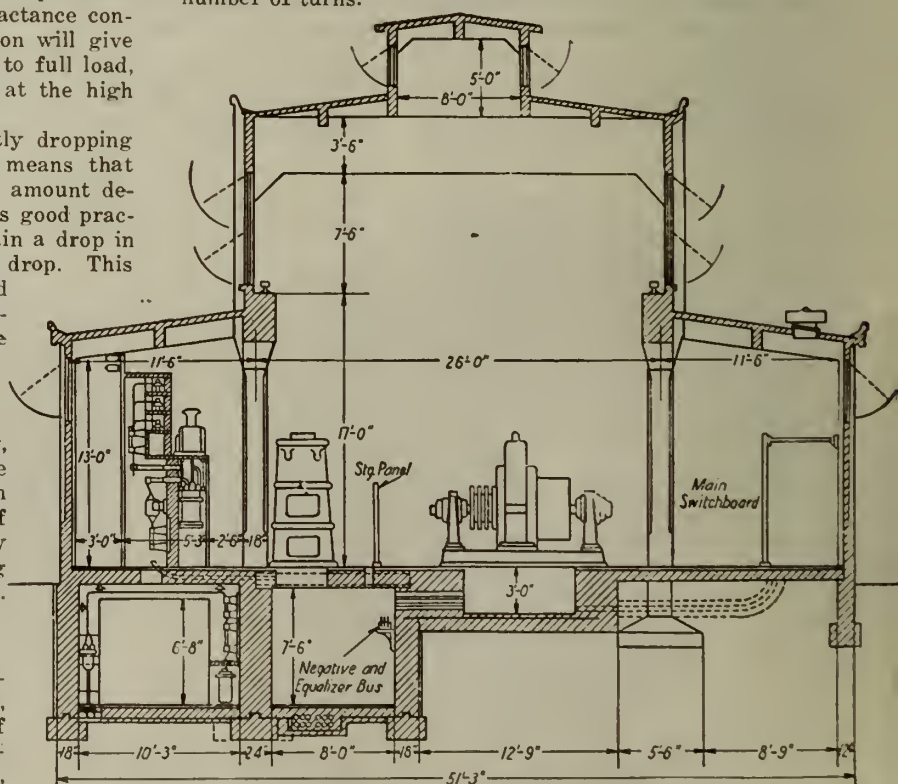


FIG. 11—UNITED RAILWAYS AND ELECTRIC CO. BELVEDERE SUB-STATION. 600 V.D.C., 13200 V. 25 CYCLE A.C. ELEVATION.

Reactance

Standard transformers are designed with 15 per cent. inherent reactance for compounding purposes. This arrangement is not only less expensive, but requires less space, reduces wiring, etc., over the older practice of supplying transformers of normal reactance with external reactance coils.

protection against insulator breakage. For underground work, multiple conductor cable with double weather-proof covering, is recommended. Where space is very limited, it may become desirable to install high tension bus, circuit breakers, etc., in cell structures, in order to equal the safety factor to be obtained where sufficient space is available. This form of construction is more common in

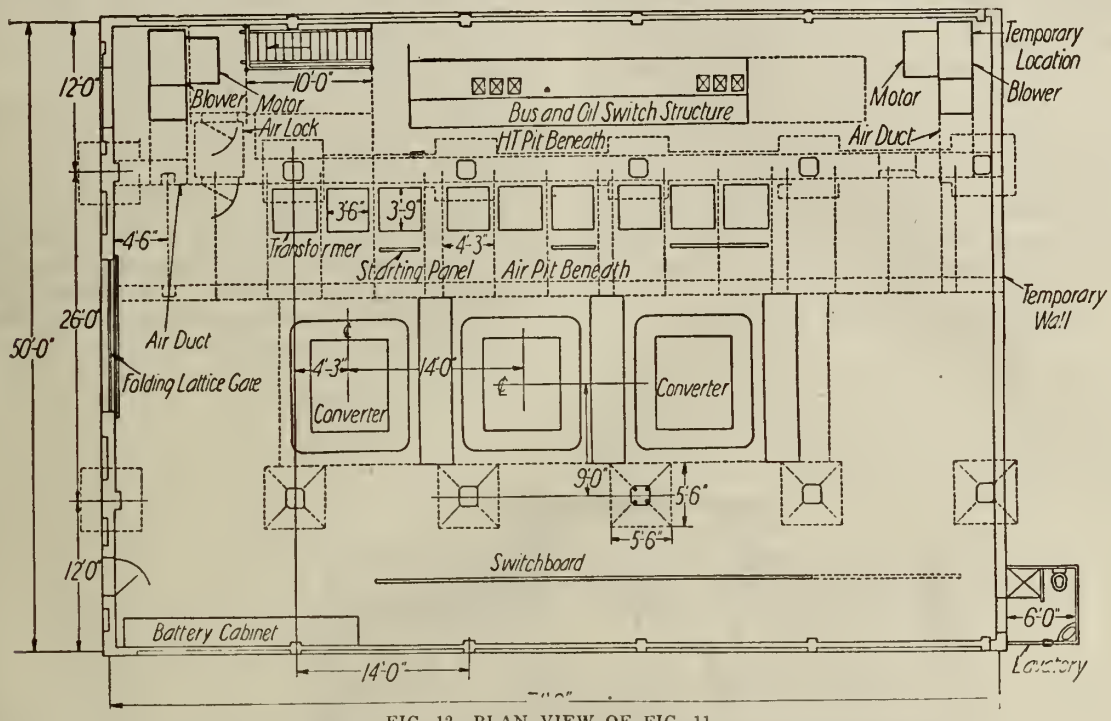

FIG. 12—PLAN VIEW OF FIG. 11.

Miscellaneous Station Equipment High Tension Wiring

Whether incoming lines are overhead or underground, it is good practice to install disconnecting switches for isolating the oil circuit breakers. Overhead lines can be brought in through roof or wall bushings or carried on suitable insulators through openings in the substation wall. Underground lines should be brought in through suitable potheads.

All high tension wiring should be well out of reach of attendants or visitors. For voltages of 22,000 to 66,000 volts, the use of solid bare copper wire, not less than No. 1 B. & S. gauge carried on suitable insulators, is good practice. Copper tubing makes a better appearance, but is more expensive. For voltages of 2,200 to 15,000 volts, the use of single conductor flame-proof copper wire, insulated with varnished cambric for full working potential, carried on suitable insulators, is good practice. Insulation is used on this class of overhead wiring, as protection against the loss of life, although it also affords additional

larger substations, fed by high tension lines of 22,000 volts and below, located in congested districts.

Low Tension Wiring

For A.C. or D.C. voltages up to 1,500 volts, the use of standard single conductor cable, insulated with varnished cambric, is recommended. Rubber covered cable is satisfactory. The cable should have a flame-proof covering, or double weather-proof covering, depending upon whether the wiring is exposed or in conduit. Care should be taken to drain all cable ducts to a pit, as it is unsafe to assume that a cable is dry, unless it is drained in this

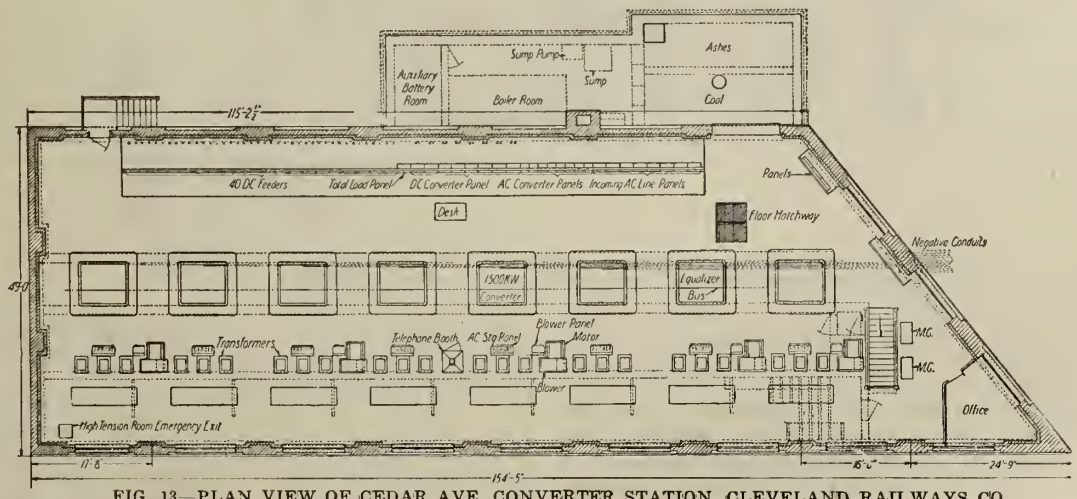

FIG. 13—PLAN VIEW OF CEDAR AVE. CONVERTER STATION, CLEVELAND RAILWAYS CO.

manner. There should be no danger of a break-down of cable in conduit, unless it is covered with water for some time.

Lightning Arresters

Continuity in service in railway work is vitally important. For this reason, and due to the comparatively high initial cost, the best protective devices should be

used. To obtain this protection, electrolytic arresters with choke coils should be installed. Lines should be protected as follows:

1. Incoming high tension lines.
2. Outgoing high tension lines.
3. Outgoing D.C. feeders.

The lightning arrester should be installed between the station apparatus and the line, with suitable choke coils connected between the station apparatus and the lightning arrester. For high tension voltages in excess of 10,000 volts, the arresters can often be installed outdoors to advantage, from an arrangement standpoint. It is undesirable to use outdoor arresters below this voltage, as the horn gaps must be placed so close to take advantage of the freedom of discharge of the electrolytic element, that they are liable to be short circuited by rain. Besides serving to prevent the arrester from being continuously subjected to normal line voltage, the horn gaps also act as disconnecting switches, when inspection or repairs are necessary.

D.C. aluminum arresters should be installed on each outgoing feed. Where installations do not warrant the use of electrolytic lightning arresters, other types may be used to advantage.

D.C. aluminum arresters have, in some cases, been used connected directly across the converter armature on the D. C. side inside the series field, for the purpose of minimizing flash-overs. Whether this practice is of sufficient value to warrant the installation apparently must yet be determined.

Compressed Air

The substation should be provided with an air compressor for cleaning the machines, high tension insulators, etc. The pressure should be from 40 to 60 pounds, and the set should have a capacity of 15 to 20 cu. ft. per minute. The compressor should be mounted with storage tank on a truck, or stationary, with a few air pipes to various points where compressed air is required.

Crane

Where the installation warrants, a crane of suitable capacity should be installed, to facilitate erection and repairs in cases of emergency. Cranes of ten tons capacity or smaller can usually be hand operated to advantage, as they are not in use frequently enough to warrant the expense of electric drive.

Where no crane is installed, roof beams can usually be located, suitable for supporting a chain fall of sufficient capacity to facilitate handling of the apparatus.

Substation Building

When drawing up plans for a substation building, full consideration should be given the following design factors:

1. The arrangement of the apparatus should be made to economize space, and reduce to a minimum the quantity of low tension cables required. On the other hand, sufficient space must be allowed around the apparatus to prevent interchange of radiated heat, for efficiently cleaning and for making repairs.

2. Careful study of the ventilation problem must be made, as it is just as important in this class of building as in an office building. Good ventilation but very slightly increases the cost of the building and materially increases the life and output of the apparatus. It increases the efficiency of the transforming and converting apparatus, since copper losses are reduced at lower temperatures and often conditions are such that the load factor can be improved. It also improves the efficiency and alertness of the operators.

The ideal system of ventilation is to take the air in at

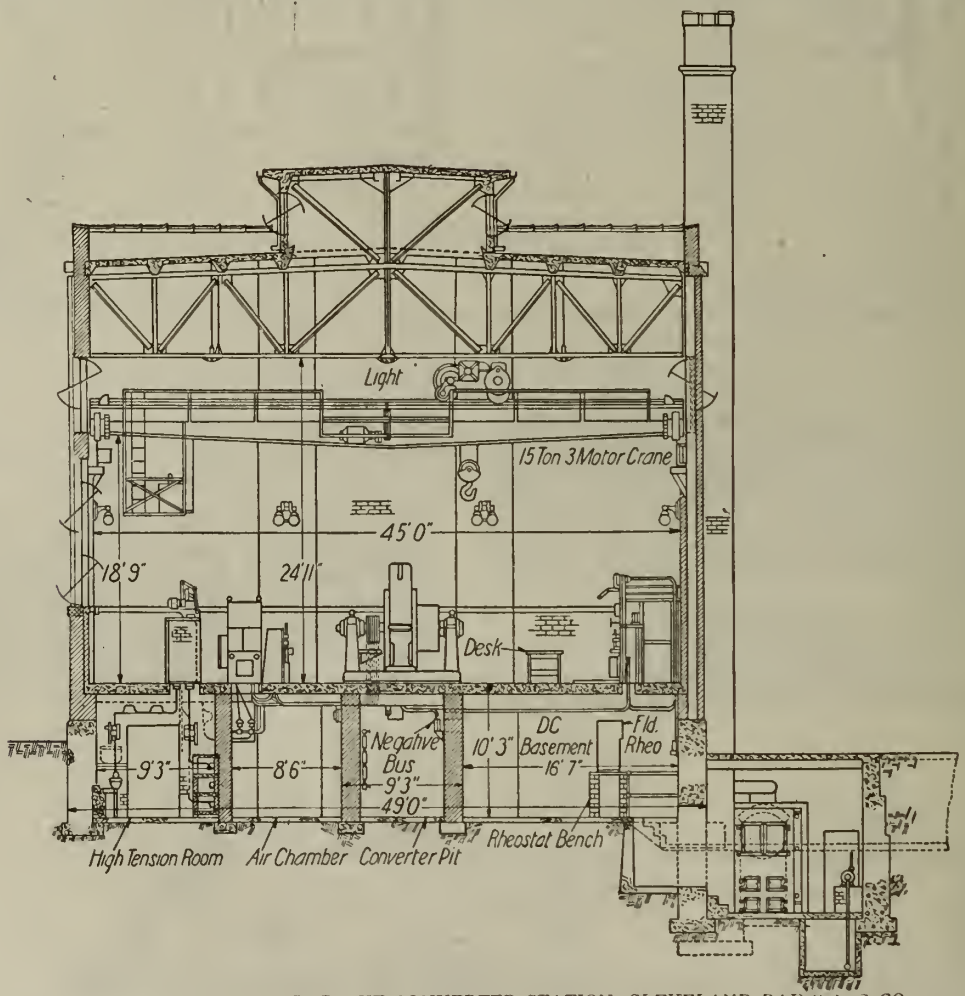

FIG. 14—CROSS SECTION CEDAR AVE CONVERTER STATION, CLEVELAND RAILWAYS CO.

the base of the machines or transformers and allow it to pass out through the roof by means of monitor construction or metal ventilators. The velocity of the warm air rising from the apparatus depends upon the difference in temperature between the incoming and the outgoing air and the height of the openings for the exit of the air above the floor. Consequently, the height of the exit openings, must be considered, although usually the required head-room will brace these openings sufficiently higher to use this ventilating scheme efficiently. Unlike the old window method of ventilation, this scheme is possible during all kinds of weather.

3. Noise from the machines, especially where substations are located in resident districts, is a point for consideration and it may become so great as to become a decided nuisance, rendering it possible for neighbors to obtain injunctions, causing a substation shut-down. The method of using open windows and doors for ventilation, is not only objectionable in many localities due to the deposit of dust blown in on the rotating apparatus, but due to noise. The ventilation scheme recommended above is particularly recommended from the noise standpoint.

4. While the window area should not be excessive, the building should be well lighted by day, in all parts to facilitate repairs so that all corners, pits, etc., can be readily observed and thereby kept clean. The use of ribbed glass is very desirable, as it eliminates the glare of the sun, making it easier to read instruments, gauges, etc. Artificial illumination should approach the natural lighting, as very often repairs have to be made at night. It should preferably be obtained by the use of lamps in large units with suitable diffusers. In 600-volt substations, a cluster of small lamps can be substituted, thereby avoiding the use of a special lighting transformer. This same arrangement can be used for 1,200 or 1,500-volt substations, but except in rare cases, it is probably better to use a separate lighting transformer. The arrangement of the lights should be made with particular reference to the easy reading of switchboard meters, transformer and machine bearing oil gauges, thermometers, etc.

5. The building should be constructed throughout on a fire-proof basis, with every arrangement practicable to protect one piece of apparatus from another and to protect all from external fire communications. In some cases, it may be desirable on account of insurance rates, or for a greater insurance to continuous operation, to increase the cost of the substation building by the cost of a fire wall to isolate the transformers and oil switches from the converters and switchboard.

6. Every provision should be made for a possible extension of the substation even though it appears that no future extensions will be necessary at the time the design is made. This refers to a symmetrical arrangement of the apparatus on the unit system and the proper construction of roof framing to make such extensions feasible.

7. The building should be simple and substantial with just sufficient paneling on the exterior to relieve the monotony of a plain wall. An attractive building can be built at the same cost as an unattractive and poorly designed one if sufficient attention is given to this point.

Indoor vs. Semi-outdoor Substations

Except in rare cases there is little saving in resorting to the semi-outdoor substation. Where a semi-outdoor installation is contemplated it is wise to investigate the relative cost, as the indoor substation presents advantages assuming approximately equal initial cost.

A cubic inch of coal pulverized so that 95 per cent. will pass through a 100-mesh screen will contain over two hundred million particles, none of which will be greater than one one-hundreth inch cube, and a larger percentage will be less than one six-hundreth of an inch cube.

A simple cable conductor has been in use for some time past, in Germany and other European countries. It consists merely of a flat metallic tube in which a series of notches are made with a special tool, after the two ends of the cable to be joined are properly inserted. The contact is said to be perfect, and the grip is such that the cable breaks before the connector gives away.

Montreal has a street cleaning device which sweeps the dirt to one side of the thoroughfare, where it is taken up by suction into a machine following up. Another feature of the road-sweeping scheme, is that sprinklers in front of each machine lay down the dust. Proving that ingenuity and machinery in unison make a wonderful combination.

Noise has no terrors for the new Magnavox anti-noise transmitter, which was used on all the airplanes of the United States Navy. This device was patented nearly two years ago, but only recently released for commercial purposes. No helmet is necessary for the listener, but still the voice is distinct whether one or one hundred miles away. E. S. Prideman, and P. L. Jensen are the inventors of this interesting telephone aid.

Nearly all animals are said to be better swimmers than man, and to take to the water naturally. The rhinoceros and hippopotamus are wonderful swimmers and divers, while the Indian elephant crosses great rivers with heavy loads. The elk keeps its head above water and crosses directly from bank to bank to avoid turning. The reindeer, on the other hand, turns as often as it likes, keeping its head only a little above the water. But of all swimmers, of all climes, the best, though not the swiftest, is the polar bear, which passes half its time in the water, swimming and diving.

The Eiffel Tower, the tallest structure in the world, was erected by Alexander Eiffel, a French engineer, for the exposition of 1889 at Paris. It stands in the Champ de Mars, and is 984 feet high (429 feet higher than the Washington Monument). The base is a square of 112 yards, from each corner of which rise the four curving supports of interlaced iron-work. At a height of 590 feet these merge into a single shaft. There are three platforms at various heights, to which the ascent is made by elevators or staircases—1,927 steps in all. The total cost was over $1,000,000, of which the State contributed about $300,000. In 1909 the Tower became the property of the City of Paris.

Valued for its weather-resisting qualities, galvanized iron or steel has long been produced by dipping sheets of the metal into molten zinc, which deposits itself as a coating of small crystals or spangles. Occasionally, however, sheets have been produced with large spangles which, it was found, improved both the appearance and the non-corrosive qualities of the product, and hence increased the price it would bring. So one plant has raised the value of its output by treating high-grade molten steel with an alloy containing titanium before rolling it into sheets and subjecting it to the zinc bath. It is claimed that 75 per cent. of the treated sheets emerge from the bath with the large spangles desired.

Out of the war shortage of tin has come a new and successful substitute for babbitt as a bearing metal. It is composed almost wholly of lead, hardened by an electrical process. Its high manufacturing cost is more than compensated for by the low market price of lead compared with tin. The new metal shows a tensile strength of 13,000 lbs., the figure for genuine babbitt being 11,000; and an elastic limit of 11,525 lb. as against 10,000 for babbitt. Its friction factor is very low. With a shaft running at 400 r.p.m. and a load of 1,000 lb. per sq. in., 150° was the highest temperature reached by the bearing.

Across 11 miles of rough country near Pittsburgh, Pa., is being constructed what is probably the largest gas line in the world. It will have a maximum diameter of 40 in., enabling it to convey 70,000,000 cu. ft. of gas daily from a by-product coke plant to three steel mills.

Saving Coal in Steam Power Plants

The Following is a Reprint of Engineering Bulletin No. 2, Prepared by the United States Fuel Administration in Collaboration With the Bureau of Mines

Isolated Plant Versus Central Station Power

If the available power purchased or privately generated is obtained purely from a hydro-electric service its use will, of course, save fuel over any steam-power proposition. If, however, in a steam plant all the exhaust steam were sufficiently utilized the boilers would still have to be operated at about 90 per cent.[1] of their former output to supply the heating steam (even if at low pressure) if the engines were shut down, and the saving in coal would be only 10 per cent. instead of 100 per cent.

B. If the purchased power is produced in a central steam plant capable of delivering a kilowatt hour for, say, 2½ pounds of coal, then its use will waste or save in comparison with a private steam plant, as follows:

B-1. If all the exhaust steam from any design of private plant is absorbed by heating and process work, no central power station[2] of condensing operation can ever be designed to compete with it in the matter of coal consumption.

If the engines in this private plant were all removed it would still require 90 per cent. as much coal as formerly to make low-pressure steam for heating, and outside current at 2½ pounds per kilowatt hour would still have to be purchased.

If the private plant had been using 8 pounds of coal per kilowatt hour it would save eight-tenths of a pound of coal, to replace which it would buy current costing 2½ pounds. Thus, for each pound saved in the private plant 3⅛ pounds are burned in the central station. This example represents the extreme case in favor of the private plant.

B-2. If the same private plant operating noncondensing wastes all of its exhaust steam, coal will be wasted in the ratio of 8 to 2½ per kilowatt used. Coal will be saved by substituting purchased power. This example represents the extreme case in favor of the central station current, and the ratio is 8 to 2½ or 3.2 to 1.

To sum up cases B-1 and B-2, the use of exhaust steam is the determining factor. Where it is all used the small private plant generates its energy as a by-product of its heating. The engine or turbine acts as a pressure reducing valve between the boiler and the heating system, and abstracts a small percentage (3 to 12 per cent.) of heat from the steam. Therefore shutting down the engine will save only this small fraction of the total coal. For most cases of this kind it is safe to say the engine absorbs less than 10 per cent. of the heat or fuel. As a matter of fact, many cases could be quoted where no saving of coal occurs when the engines are shut down[3].

[1]Exhaust steam contains, within a few per cent., as much heat as direct steam. Thus an engine or turbine with steam consumption of 20 pounds and 60 pounds per indicated horsepower hour will discharge in their exhaust about 88 to 96 per cent. of the heat of the steam admitted at their throttles respectively. In the examples given 90 per cent. is assumed.

[2]Operating condensing in accordance with standard practice. If a central plant were designed to furnish exhaust steam to its customers it could then compete on a coal basis with the private plant. This is the sound theory of the "city block" or "district" system of power and heating.

[3]There are sound technical explanations for these cases, but it is aside from present purposes to enter into a detailed discussion.

[4]The proportion of exhaust required for heating represents almost the same proportion of coal which will have to be burned for direct steam heating if the engine is replaced by purchased power.

[5]Equal coal consumption obtains when the proportion of total coal required for heating alone equals one minus the fraction obtained by the ratio of the kilowatt hour coal consumptions of the isolated plant to the central plant figured from the purchaser's switchboard. Example: With purchased current at 4 pounds of coal and private power at 7 pounds, an equal coal consumption with either system will obtain when the proportion of coal required for heating is 1 minus 4/7 = 3/7 of the total coal.

Hence for purposes of approximate calculation the power is a pure by-product of the heating. But assuming 10 per cent. of the heat of the steam to be taken by the engine, then only 10 per cent. of the coal consumption will be saved if the heating is done by direct steam. Eight pounds of coal per kilowatt hour, the figure assumed, is based upon an extravagantly wasteful boiler plant, but even under these conditions the small private plant using all its exhaust would save coal over central station current for power ratio of 3⅛ to 1.

If on the other hand no exhaust steam is used in the same private plant, the saving in favor of the central station power is in the ratio of the coal used per kilowatt hour for the two cases, or with the figures assumed, 8 to 2½, that is 3.2 to 1.

It is evident that in a noncondensing private plant, as the use for exhaust steam decreases a certain point will be reached where the same coal consumption would obtain by the generation of power by either type of plant. A still further reduction in the utilization of exhaust would then throw the balance in favor of central station power.

This critical point of equal total coal consumption depends upon the coal consumed per kilowatt hour in the private plant and the central plant, respectively. Thus if the central station has a coal rate of 3 pounds per kilowatt hour and the private plant 6 pounds, the critical point is reached when 1 minus 3/6=1/2 of the exhaust or coal is needed for[4] heating, and the same total coal will be consumed whether the power is purchased of the engine operated. If less than one-half of the exhaust is used, the purchased current will effect a saving; if more than one-half of the exhaust is used, running the engine in the private plant will save coal.

Take another case and assume that current can be supplied at the purchaser's switchboard for 2 pounds of coal, and that the small plant produces it for 5 pounds. Then, if 1 minus 2-5 = 3-5 of the coal or exhaust is needed for heating no change in total coal consumption will occur if current is purchased, the engines shut down and boilers operated for heating only[5].

If the coal per kilowatt hour for outside current is less than the same figure for the private plant, the most coal will be conserved by carrying just enough load to furnish exhaust for the heating and buying the surplus power. Thus the small plant obtains a part of its power as a by-product of its heating and buys the balance for the least total coal consumption. This method saves more coal than shutting down the small plant entirely, even when a saving would be thus effected. There are many cases where at night or during non-heating months where an important coal saving can be made by buying the power which is in excess of that required to furnish exhaust for heating.

Still another situation is met when the private plant is of modern design and operates solely for generation of power. Such cases would be determined purely on a comparison of the coal consumed per kilowatt hour. Central station power is produced at consumers' switchboard from a minimum of about 1¾ pounds of coal in the largest and most modern plants up to 3 pounds, 4 pounds, 5 pounds, and upward in less efficient stations.

In moderately large private plants of good design a kilowatt hour is produced for a little over 2 pounds, while less efficient and smaller plants consume up to 10 pounds and over. In this whole problem it is necessary to regard coal as the basis of economy and not money as heretofore. Central station interests and private consumers should patriotically endeavor to meet each other half way in sacrificing by reduced rates or increased expense when important economies in coal are at stake.

PART II

After due consideration has been given to the question brought out in the previous discussion and if it has been determined that the plant is justified in continuing to operate, attention must be given to those points having a bearing on economical operation. No transformation of energy can take place without appreciable loss, and every effort should be made to keep the various losses down to a minimum. Diagram A shows a typical distribution of heat in a medium-sized hand-fired plant.

Stopping Fuel Waste

Beginning at the grates upon which the fuel bed rests, see that the air spaces are properly proportioned to avoid loss of combustible material into the ash pit. This will depend on the kind of coal used. Study the fuel with this point in mind. Five per cent. is not an unusual loss from this cause.

The amount of grate surface is important, as it determines the rate of consumption. Ratios of grate area to boiler heating surface will vary from 1:35 to 1:60, depending on the characteristics of the coal and whether hand fired or stoker fired. For power purposes in hand-fired plants do not permit the rate of combustion to fall below 15 pounds of coal per square foot of grate surface per hour, or go above 28 pounds with bituminous coal. With stokers the rate may be as high as the design of plant and the draft will permit. With the fine-steam sizes of anthracite the rate of comparison should not be less than 10 pounds.

With settings tight to prevent infiltration of air, heating surface clean, radiation losses reduced by proper covering, piping and steam mains lagged, engine valves tight and properly set, all condensation returned to the feed-water heater a good start will have been made in fuel conservation.

Human Element Important

However, merely placing the plant in good physical condition will not suffice. Conditions change from day to day, from hour to hour, even from moment to moment. These changes must be interpreted, and the degree of intelligence with which they are interpreted marks the degree of success which will be realized in fuel saving.

A good plant poorly operated will show low efficiency, while a poor plant skillfully operated will sometimes show a relatively high efficiency. Therefore,

Ultimate efficiency = E × H

Where E = Equipment

and H = Human element.

Check Operation Closely

Find out what the boilers are doing. Provide facilities for weighing the coal; for measuring the feed water; for checking up on combustion; for determining draft; for taking temperature readings at important points. To appreciate the significance of the above items it is desirable to become familiar with the literature of power-plant operation. Read Bulletin No. 1 of the United States Fuel Administration on Boiler and Furnace Testing, Technical

Paper No. 80, and various other publications of the Bureau of Mines. In small and moderate sized plants, hand fired, a boiler efficiency of 60 and 70 can be expected, while in medium-sized stoker-fired plants 70 to 75 per cent. should be realized. In any given plant determine what efficiency should be expected, considering load and equipment, and keep the plant up to mark set.

Principal Losses

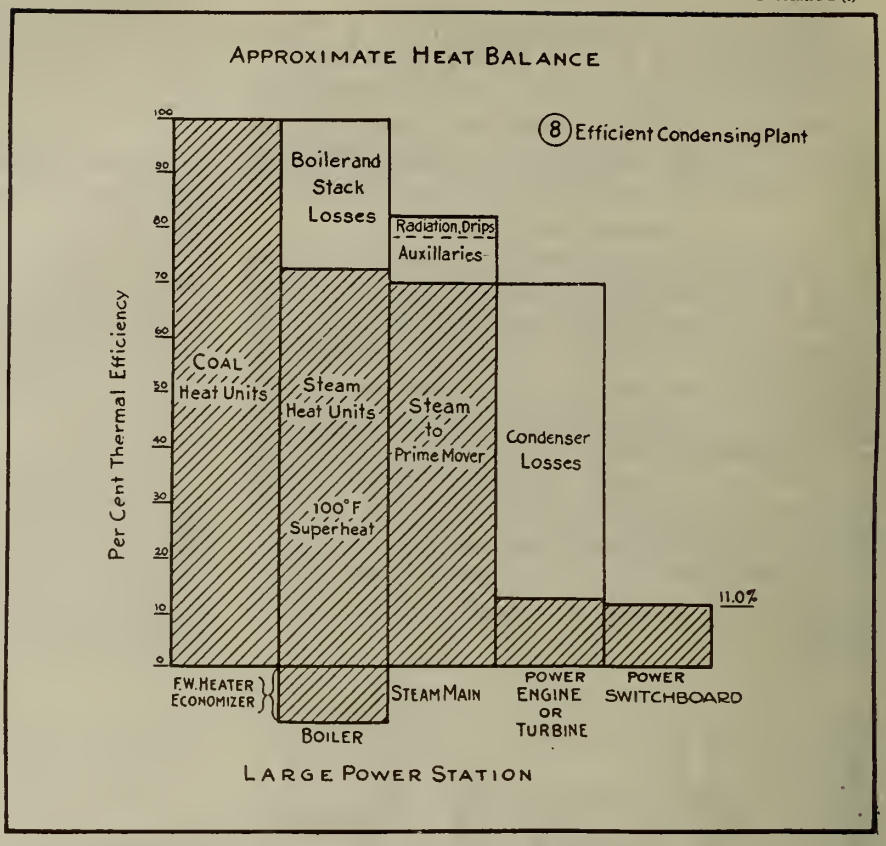
The chief losses in boiler-plant operation are:

1. Cause, dirty boiler, loss up to 25 per cent., remedy, clean boiler. 2. Leaky setting, loss up to 15 per cent., remedy, tight setting. 3. Poor firing, loss up to 40 per cent., remedy, good firing.

1. A boiler may be dirty on the inside or outside or both. Dirt on the inside is due to scale formation and can be corrected by cleaning the boiler and then giving consideration to the character of the feed water and its proper treatment. See Engineering Bulletin No. 3 of United States Fuel Administration.

Outside cleaning must receive careful attention. A slight accumulation of soot deposited in a few hours' run will result in a great loss of efficiency. Someone must be delegated to follow up this matter of soot and see that the cleaning is done thoroughly, frequently and regularly.

DIAGRAM B (c)



2. Air leaks reduce efficiency. The ordinary brickwork setting develops cracks and crevices which allow a considerable amount of air to enter the setting, lowering the temperature of the gases of combustion. The porous character of the brick itself is such that an appreciable leakage takes place through the walls.

The remedy is to point up the brickwork with plastic fireproof mixture and paint or cover the setting with a coat of air-tight material.

3. Bad firing includes allowing holes to develop in fuel bed; carrying an uneven fire; carrying too thin a fire; carrying too thick a fire; stirring fire, thus forming clinkers; and improper manipulation of dampers. It is here that the human equation becomes of most importance. Attention concentrated on what takes place from day to day in front of the boilers will pay greater returns for the time spent than in any other part of the plant.

Power Plant Records

The importance of keeping a systematic record of operations can not be overestimated. In this way affairs in the power plant are lifted from the realm of guesswork to certainty. While the system adopted for the ordinary plant may be very simple, the records should be arranged for convenient reference so that comparisons of results with past performance may be made. Thus it is possible to note the effect of changes in equipment or methods and improvements in economy or the reverse may be at once detected.

Engine Room

After the steam has been delivered to the engine, care should be taken to see that it is utilized to best advantage. Where all the steam is needed, the economy or rate of the engine itself is not of particular consequence; that is, a simple slide-valve engine using steam at the rate of 40 or 50 pounds per horsepower may be the most desirable type to use. This all depends on circumstances. As the demand for exhaust steam decreases, the importance of economy in the engine increases. Should there be periods during which all of the exhaust is not used, the maximum economy of the engine during these periods is of utmost importance. At such times the most economical generating unit should be selected and one of a size that will be economically loaded with the amount of power developed.

Use of Exhaust Principal Factor

A portion of the exhaust should be used for heating the feed water to the highest temperature practicable; not less than 200° in any event.

Exhaust mains should be pitched in the direction of flow, drained and trapped, and the condensation returned to the heater. Use no live steam where the work can be done with exhaust. To get the most efficient transfer of heat the radiating surface of coils and other heating elements should be properly disposed to promote circulation of the heat-absorbing medium, whether air, water, or other liquids. Large increase in efficiency or capacity can sometimes be made in old systems by a little attention to this feature.

In the case of stills, evaporators, or triple effects in which deposits of suspended or residue matter is liable to form, periodical cleaning of the coils is essential.

Venting radiators and steam lines of air should receive careful attention. See Engineering Bulletin, No. 6, on Saving Fuel in Heating Systems. For large systems vacuum returns are recommended. Direct radiation should be checked up with special respect to location in order that heat loss through exposed walls and windows shall be taken care of efficiently.

A study of the accompanying heat balance diagram will serve to indicate the small portion of the heat developed by the fuel which is used in generating power.

Do not, therefore, assume that the steam after passing through the engine is a waste product. It will represent a large percentage of the heat delivered by the boiler. Save it wherever possible. It is the principal product of the plant. The power is the by-product.

A WOMAN conductor on a New Jersey street car was kind to an old man and got $6,000 in his will. The only trouble with this is that most old men with $6,000 have about 60,000 places to put it.

U.S. shoemakers say that each immigrant who returns home to Europe takes eight pairs of shoes with him. The Yankees are in danger of losing their soles in this way.

Cheese Factory Boiler Explodes at Joyceville

Little Village Near Kingston is Scene of Disastrous Explosion—Boiler Ruptures Along Longitudinal Seam, Which Was Badly Corroded—No Inspection Had Been Made on This Boiler Since Installation

T. H. FENNER, Associate Editor Canadian Machinery

THE question of the adequate and regular inspection of steam boilers is once more brought to the public mind in a way that defies evasion. Once again a boiler in an industrial plant has exploded without a minute's warning, leaving in its trail a wrecked building, and worse still, destroying two human lives. Both the victims were young men, with many years of life in front of them under ordinary circumstances.

The boiler in question was in use at the cheese factory of Thomas Anglin, of Joyceville, and was of the horizontal return tubular type, about 38 inches diameter. It was similar to most of the cheese factory boilers, of which there are no less than one thousand and forty, known and listed in the Factory Inspection Department. There are probably many more than this in use, for it is a difficult matter to keep track of these boilers. Under the Factory Act, steam boilers in use on farms, or for general agricultural purposes, are exempt from inspection. Cheese factory boilers were at one time also exempted, but for some years past they have been brought within the law.

The original thickness of the plate was ¼ inch, and the boiler was made up of two sheets, the longitudinal seam being single riveted. We have no particulars of the pitch, but with a joint of this kind the percentage of strength to the solid is approximately 50 to 54. On this assumption the resistance of the shell to internal bursting force would be, with a factor safety of 5, about 70 lbs. if made of steel. This, if the boiler was in good condition, which it was not.

Some interesting statements were made at the coroners' inquest relative to the operation of the boiler. It had been installed in 1915, having previously been in operation for some time. The owner was supposed to have notified the Steam Boiler Department at that time, but presumably was not aware of this. It was not until two years after that he received a circular from the Factory Inspection Department, notifying him that an inspection was necessary. He then called in a local firm, who made a repair by patching the boiler. The repair people undertook to notify the Inspection Department, and apparently did so. The inspection was not made for reasons given later in this article. The owner thereupon let things slide, evidently believing it was no affair of his. He continued using the boiler, and finding that the safety valve opened at about 40 lbs. pressure, hung some more weights on the lever, to bring the pressure up to 80 lbs. It was stated that the boiler actually blew off at 100 lbs. per square inch. At the time of the explosion, the pressure was stated by Edward Gallery, the cheesemaker, to be between 80 and 100 lbs.

This man was presumably the operator of the boiler. He had received some instruction in boiler operation while taking his course for cheesemaking. He was not aware that any inspection was necessary, and stated that he never heard of inspections being made in other cheese factories.

Here we have the two men most interested in the boiler, one the owner and one the operator. The owner knew that the boiler should be inspected, but, when the inspection did not materialize, took no steps to find out why. The other man had no idea that the boiler needed inspection, and cheerfully went on operating without the slightest conception of the danger he was running. When the catastrophe took place, it was two men who were not even employed at the factory who were killed. There is an instance of fate's irony.

The provincial inspector, who made an examination of the remains of the boiler after the accident, found evidence of deep corrosion on the seam where the rupture took place. The plate was grooved until a bare one-sixteenth of an inch thick. He stated that the boiler was poorly built, and when new would have been good for only 54 lbs. per square inch. If it had been inspected by him he would have condemned it, or allowed only 15 lbs. per square inch.

Two weights were found which had been on the safety valve lever. Had they been at the end of the lever it would have required a steam pressure of 200 lbs. per square inch to raise the valve. The steam gauge, never having been tested, may have been considerably out, and probably was.

Here is a case where, had the inspection been made, the accident would have been prevented. The reason given for not making the inspection is a shortage of inspectors, there being only six for the whole province of Ontario. In the case of cheese factory boilers, the difficulty of inspection is enhanced by the out-of-the-way localities they are usually placed in. This makes the inspection a matter of a whole day in some cases, and when the number of boilers are considered, it is quite to be understood that some of them are missed. There are many owners of boilers who take no interest in the safety of their property, either through ignorance, or a desire to save the fees. There is a great need of a means to enforce the laws already in existence. In this connection a good plan has been suggested. It is that instead of having the inspectors all atttached o the central office, the province should be divided into districts, with a resident inspector in each. This inspector would know the district and everybody in it, and the possibility of a boiler being operated without inspection would be reduced to a minimum.

It would also prevent a thing that frequently happens now. A man has a boiler on his farm which comes under the agricultural classification and is, therefore, exempt from taxation. He takes up cheese manufacturing, or starts a sawmill, and the boiler is then, of course, in commercial use, and liable to inspection. If the owner himself does not notify the Factory Department of the change, it is quite probable that under the existing conditions he may operate it for one or two years before anything is known about it. Resident inspectors would know of a case of this sort immediately.

The Case of the Farmer's Boiler

This brings us to another consideration. Why should any steam boiler be exempt from inspection merely because it is not used for commercial purposes? A farmer who uses a threshing engine, or steam tractor, is not compelled to have it inspected.

The viewpoint of the Legislature is presumably that a man using a boiler on his own land for what may be reckoned as purely domestic purposes, should not be bothered with inconvenience of Government supervision.

Speaking generally, the less the Government interferes with private enterprise, the better; but here is a case where it is in the interest of the man himself to interfere. The law puts effective checks in the way of the purchaser of poison, even if only to kill vermin, or a dog who has had his day. It should do the same with such a highly dangerous instrument as a steam boiler.

There is a very wide spread fallacy among small steam users that because a boiler is comparatively small and operating at low pressure it can't do much damage anyway. They are partly right. A 30 inch diameter boiler operating at 100 lbs. pressure is not so dangerous as a 60 inch boiler operating at 50 lbs. pressure, but it is dangerous enough. The explosive force of a boiler lies not in the pressure it carries, but in the heat energy contained in the water. The greater the weight of water, the greater the damage that will be done. This

Another Fatal Explosion

ONCE again the peaceful life of a little village has been violently interrupted, and sudden death and disaster descended without warning on the unsuspecting inhabitants.

The instrument of destruction this time was the small boiler in the cheese factory of Thomas Anglin, of Joyceville, a little village about twenty miles from Kingston. The boiler, which was being operated at a limit far beyond its safe working pressure, ruptured suddenly along a seam which was afterwards found to be corroded down to a thickness of only one-sixteenth of an inch.

Nobody in connection with the establishment knew anything about a boiler and the boiler had never been inspected since its installation four years ago. The boiler was not then a new one, and according to law, should have been inspected. Two years after installation a circular was received from the Factory Inspection Department, notifying the owner that inspection was necessary. This was his first inkling of anything of the kind. He called in a local firm who put a patch on the firesheet, and this firm, in accordance with the requirements of the law, notified the Boiler Inspection Department.

The chief boiler inspector replied, saying that he was willing to allow the boiler to be put in operation, and would instruct one of his inspectors to examine it on the first occasion he should visit the district. Two years elapsed, and the boiler exploded before that inspection took place.

The failure did not take place at the spot where the repair had been made, but at the longitudinal seam which was wasted away. An inspection would have discovered this wasting. The safety valve was loaded too high. An inspection would have determined the safe (if any) working pressure.

The reason advanced for non-inspection is that there are not enough men on the inspecting staff to do the work. Surely the Government of Ontario can afford to employ sufficient inspectors to protect life and property. There are considerably over one thousand cheese factory boilers in the province. How many of them are unsafe?

Buried Treasure Again

THE uncovering of lost treasure from the bed of the ocean has exerted a fascination over the minds of men from early times. From day to day new schemes for salvaging sunken vessels are sprung on an expectant world, to dazzle susceptible minds for a few brief moments and then fade away from sight and memory. Most of these schemes would be perfectly practicable if it were not for certain fixed and immutable laws of nature. One of the most important of these is that every 2.3 feet depth of water exerts a pressure of 1 lb. per square inch on the surface of any object immersed in it, the effect of this pressure being to set very definite limits at which diving operations can be conducted.

One of the latest of these schemes has been evolved by the United States Ship Salvage Participating Syndicate. They have borrowed the famous tank from the battlefield, and are going to ask it to become an amphibious animal, and conduct constructive work on the bottom of the sea, instead of destructive work on the surface of the land. The tank can be built with strength to withstand the pressure of the sea at whatever depth it is necessary to operate. It will be directed from above electrically, and in order that the operators can see just what it is up to, an instrument called a "subsea visionscope" has been invented. The idea is that the tank will be lowered to the bottom of the sea, carrying wire cables, the ends of which are brought up to the surface on each side of the sunken vessel. All being ready, the operator on the surface applies the current, at the same time keeping a watchful eye directed down the subsea visionscope. The tank immediately gets busy burrowing under the wreck thus passing the cables under her bottom. Air containers are attached to the ends of the cable and inflated, upon which the buoyancy of these air vessels raises the vessel from the bottom.

Could anything be simpler?

Here is a chance for those who are getting bored with the tameness of the mining market to get a little quick action. The syndicate is going to be capitalized at $5,000,000, in $1 shares, so there is really no reason why everyone should not get in.

Now that one cannot put a little bet on an "also ran," the romantic interest of these salvage operations should have an appeal all its own.

HAVE YOU LOTS OF FRIENDS?
By H. J.

If you have, then all is Jake, as the saying goes.

If you have not—then something is out of kilter.

Is this your trouble?

Are you inquisitive, and keep sticking your nose into other people's business?

Do you repeat all the gossip tales you hear of?

Did you ever haw! haw! at some religious belief you've heard suggested?

Do you carry a grouch around with you?

Have you ever knocked someone, simply because they possessed some quality you haven't got yourself?

Do you tell your troubles, and speak of your aches to every Tom, Dick and Harry that you meet?

Do you try to convince everybody that this old world is all built wrong, and that you've been lost in the shuffle?

If you have spilled any of the above remarks from time to time—no wonder your friends are few.

A considerable vein of pitchblende, from which radium is extracted, has been discovered near Buckfastleigh, in southern Devonshire, England. The ore yields over 26 per cent. of uranium oxide, and the lode will be developed immediately.

* * *

A very effective dust catcher for surface grinders consists of an iron bracket, to which is bolted a broad piece of sheet metal, with a water pan or trough built on at the bottom. A piece of heavy cloth, or burlap, is hung over the sheet-metal surface, long enough to reach down into the water trough. The burlap soaks up the water like a wick, and is always kept wet. Emery dust and small metal particles thrown against it are caught and kept from flying around the shop.

* * *

Wealthy tourists to St. Moritz, the world-famous Swiss winter and summer resort, may soon be able to make the trip from Zurich in one hour, instead of the seven or eight now required by the railroad. Capitalized at about $100,000, a company has been formed to back the 90-mile airplane line, and has already announced that service will be inaugurated during the year with tickets selling at about $100. Many will doubtless be willing to pay this price, if for nothing but the matchless view of mountains, lakes, and glaciers.

* * *

A newly developed steel that seems particularly desirable for dies, taps, and other cutting tools, changes its form so little during the hardening process that castings have the appearance of smooth forgings, and need almost no machining. The texture is uniform and close-grained, and castings may be subjected to high temperatures without scaling. Because of this heat-resisting property it is claimed that the walls of annealing boxes may be made much thinner with this material, and that the original shape and weight is retained through many more firings than when malleable or cast iron is used.

* * *

A novel kind of lock nut, which cannot be accidentally loosened on the bolt, but is readily removed with a wrench, has been designed by a woman inventor. A recess in the top of the nut is shaped at the bottom like a shallow spiral stairway. The nut is turned onto the bolt, and a short cotter pin is inserted through a slot in the bolt. Tightening the nut engages the pin with the notches or "stairs" of the recess, which position it holds until forcibly disengaged. With the cotter pin removed it acts as an ordinary nut.

* * *

MANY people spend a great deal of time wondering why the Government, or some other organization, does not go ahead and deal with the cold storage. We heard of one man who spent three days going around getting signatures to protest against storing eggs. The same amount of effort, together with a crock and some water-glass, would have given this well-purposed chap a cold storage plant of his own, and would have made the doings of the cold storage people a matter of indifference to him.

* * *

Pottery ware which is to be subjected to kiln fire is placed in rough clay boxes, called "seggars." Ordinarily made by hand, these articles can now be turned out by an electrically-driven press, which increases the capacity of a man and helper about tenfold. The operator places a piece of plastic clay in the mold, pushes it under the press, and moves the lever forward. The screw brings the top plunger down, and presses the seggar; after which the machine reverses itself and comes to a stop at the proper height. Pulling the mold back, the operator pushes out the seggar by means of the geared ejector.

* * *

Liquids and solids do not ordinarily mix, and the idea of combining coal and petroleum to make a new fuel sounds rather chimerical at first. Yet that very thing has been done, and successfully, by pulverizing the coal so finely that it forms a colloidal, or suspended, mixture with the oil. This compound passes freely through all regular oil pipes and burners, so that it can be used for power and heat without equipment change; and it generates a greater heat value than oil alone. Coal dust, passed through a 200-mesh screen, mixed with a little tar in the oil, leaves no deposit even after months. Use of the new fuel in place of fuel oil on sea and land would save millions of barrels of oil a year.

Tinkerin' John

HE was just a sort of a handy man as he canted around the plant, and everything got done the same with a kind of a skip and a hop. He did odd jobs and just filled in whenever a chap was off, with the gout or rheumatiz or such, or nursin' a graveyard cough.

But they'd never give him a steady job, this tinkerin' chap named John, for fear that somethin' he turn or do would have a chance to be wrong. So he puttered around at this and that, and he worked from bell to bell, but Tinkerin' John could never do a particular job real well.

Oh, Ive seen a heap of tinkerin' Johns; you meet them East and West, and they couldn't, to save their bloomin' hides, name the job they could do the best.

They can tinker at this and tinker at that, and they're handy to have around, and they always stay on the ladder quite near where it hits the ground. And when there's a chance to go higher a bit, where pay is both thick and long, they never turn to give a chance to this here tinkerin' John.

Oh, I've seen a heap of tinkerin' Johns; you meet them up brown, and do it better than any chap what's campin' in the town. It's great to see the hand of skill linked up with a mind that's keen; that can take any job that comes along, the fat as well as the lean—and can do the thing bang up each time with never a flaw to spoil—it's chaps like them that help to bring real honor to honest toil.

But tinkerin' John, he's always here, just fiddlin' his years away; a sort of a handy chap to have and never one hard to pay.

There's a bit of a sermon here for you—don't dodge nor pass it along—if you want to get to the top of the heap don't be just a tinkerin' John.—ARK.

INDUCTION MOTOR TROUBLE

By W. F. S.

A case of induction motor trouble, which offers some interesting features, has recently come to our attention. The particular motor was only of three horsepower, 25 cycle, 220 vol, three-phase type, and was connected to a shell conveyor inclined at an angle of about 30 deg. through chain drive. It was noticed that the motor stalled quite frequently owing to pieces of steel jamming in the delivery end of the elevator. When this happened the motor very accommodatingly ran backwards and picked up speed in the reverse direction. It was thought at first that the weight of the conveyor, loaded as it usually was with shell billets, was the cause of this reversal of direction, the weight being sufficient to run the motor backwards. This, however, proved to be incorrect, as the motor and conveyor remained stationary when the motor switch was opened and the conveyor loaded to capacity. In fact, a couple of huskies with crowbars were unable to move the equipment.

The motor proved so accommodating that it was decided to try its possibilities out still further, and the conveyor was arranged so that it would run in the forward direction a short distance and then jam. If the motor reversed and the conveyor ran backwards, it would again run freely for a short distance before jamming again. The motor lived up to expectations and a regular seesaw action resulted.

The solution for this peculiar motor action was found in the fact that one of the fuses was blown on the running side of the double throw switch used for starting and running, the starting side being connected in solid without fuses. The motor was started by means of three-phase current in the usual manner, but when the starting switch was thrown over to the running position only single-phase current was available for operating the motor. This served the purpose in a fairly satisfactory manner, but when the motor stalled, due to the conveyor jamming, it would ordinarily be unable to pick up and run in either direction. A three-phase motor will not start on a single-phase supply of itself, as no rotating field is produced, but only an alternating one, which is fixed in position. When, however, a three-phase motor, fed with a single-phase current, is given a slight rotation by any outside means, it will pick up speed and run in either direction, depending upon the impressed rotative effort. This rotation is accounted for by means of the rotating elliptic field set up by means of the action of the induced rotor current on the field magnetism.

When the conveyor jammed in either direction the elasticity of the conveyor itself and in the chain belt was sufficient to give the motor a slight rotation in the opposite direction, and this sufficed to give it all the start it needed.

One point should here be mentioned in the testing of fuses when applied to induction motor protection. The fuses should be tested out by means of lamps, or some other method with power off, as with the motor running both sides of it a dead fuse will be made alive, the one from the line and the other through the motor.

STORING AIR IN THE EARTH

A novel method of providing a receiver of unusually large capacity for compressed air was described by Mr. N. Knapp in the course of the discussion of a paper on natural gas storage, read before the American Institute of Mining and Metallurgical Engineers. Mr. Knapp required a supply of compressed air for working pumps used to raise oil from wells and for blowing out the oil from the wells directly. He connected up an old exhausted well to the air compressors, and for a period of seven years used the well as an air receiver. With this storage system, many times the capacity of the air compressor could be used for short intervals without any appreciable loss of air pressure, and when no air was being used there was no appreciable gain in pressure. Two two-stage compressors were used with approximately 200 horsepower gas engine capacity, running twenty-four hours per day. The original rock pressure of the depleted sand was 305 lb., and the open flow capacity of the well as a gasser was about 2,000,000 cubic feet per twenty-four hours. When the air was pumped into the well, the gas had been used down to a rock pressure of 115 lb., the production was small and the gas was wet and troublesome to use. In the course of a few months' use of the compressors, a rock pressure of 290 lb. of air was developed and there was no water trouble. The extent of the sand used for air storage was small, probably not over 20 or 25 acres, as shown by dry holes and exhausted wells. The thickness of the porous gas sand probably did not exceed 7 ft. The occasional gas sands of this region, Mr. Knapp imagines, were like isolated hillocks of sand resting on the salt-water sand that underlaid the whole country. The depth to the gas sand was about 800 ft., and it underlaid the oil sand.

BOILER EXPLODES AT JOYCEVILLE

Continued from page 341

Joyceville boiler was of the kind usually reckoned by the farmer class to be without possibilities of danger. The accident clearly shows what a small boiler can do if it explodes.

The Remedy

The remedy is so obvious that it hardly needs suggesting. It is the plain duty of the Government to put its inspection departments on a basis that will enable them to keep track of every steam boiler in the province. Where there is danger to life, petty economies should not be considered. Five or six inspectors for a province the size of Ontario are hopelessly inadequate, and it is to be earnestly hoped that steps will be taken before any more fatalities occur

* * * *

Mixing dry colors in ready mixed paint with the ordinary paddle to get the desired shade is a decidedly tedious job and unless thoroughly mixed will be streaked and spotted when applied with a brush. A much quicker method of accomplishing the mixing is to use an egg beater, which also eliminates the skin and other foreign matter from the liquid.

* * *

The British Government has decided to offer a prize of $10,000 for a process of making a mixture of dehydrated coal tar with mineral petroleum oils suitable for Admiralty use as fuel oil. This will be awarded to the first competitor submitting a successful process which must be capable of ready and economical application without undue absorption of material and labor.

* * *

The metal layers of an engine that come in contact with one another rub off small articles of matter that combine with the lubricant used and form a dirty and sticky mess. The olein contained in the lubricant will in course of time form an acid, known as oleic acid, which has a deleterious effect on the metal parts that it touches, causing progressive corrosion. But luckily, it is only when its oleic-acid content exceeds one-quarter of one per cent. that an oil becomes unfit for lubricating purposes.

* * *

Celluloid articles can rarely be restored to their original whiteness if they have been thoroughly discolored throughout, but if merely superficially discolored, wipe them with a woollen rag wet with absolute alcohol and ether mixed in equal proportions. This dissolves and removes a minute layer of the surface being cleansed and lays bare a new surface. To restore the polish rub briskly with a woollen cloth and finish with silk or chamois. A bit of jeweler's rouge will greatly facilitate matters.

* * *

Regulations have now been laid before the British Columbia Legislature in which there is to be the provision that every winding rope shall be given a bath in hot oil before being installed; that every winding rope shall be recapped at intervals of not more than six months; and that no winding rope which has been in use for more than two years, or which has been spliced, shall be used for raising or lowering persons. No cable is to be used for more than two years for raising or lowering persons. In this country the Royal Commission on Mines in 1909 recommended that winding ropes should be allowed to be used for three years and six months. To prevent crystallization of chains it will be provided in the new B. C. regulations that all cage chains in general use shall be annealed once at least in every six months, and detaching hooks shall be cleansed and refitted once in every three months.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

Readers are invited to send in answers to these problems, as they have been chosen for their interest and application to the practical side of power plant operation.

Perhaps you, too, have some pet problems, or hard nuts which you would like to ask your fellow engineers; if so, send them along for the benefit of others.

Answers, together with the original question, will be published in the issues following the appearance of the question.

Questions Before the House

47. What is the object of the safety valve?

48. How should a safety valve be connected to a boiler?

49. How are safety valves, in practice, adjusted for a given steam pressure?

50. What is the object of a gauge-cock?

51. What is the purpose of water alarms and fusible plugs?

52. What is the object of running boiler feed-pumps at a slow speed?

53. What is combustion?

54. What is the principal element in the composition of all fuels?

55. How many pounds of water at 212 deg. can be evaporated into steam at the same temperature by a pound of coal of the following composition: Carbon, 74 per cent.; hydrogen, 8 per cent.; oxygen, 5 per cent., and ash, 13 per cent.?

55. In what way will the presence of sulphur in steel affect the latter?

56. What joint in a cylindrical boiler is subjected to the greater stress?

57. What is the bursting pressure of a seamless steel tube 12 in. in diam., 3-16 in. thick, and having a tensile strength of 64,000 pounds per sq. in.

58. What is the working pressure allowable on a boiler shell 60 in. in diam. and 11-32 in. thick, if the material has a tensile strength of 60,000 pounds per sq. in. and the longitudinal joints have an efficiency of 87 per cent. The factor of safety is 5?

59. If 2½ in. stay-tubes are placed 10 in. centre to centre, what area will each tube support?

60. A flat boiler head is supported by end-to-end stays placed 12 in. centre to centre and having nuts on both sides of the head, which is ¾ in. thick. What working pressure is allowable?

61. With a steam pressure of 160 pounds per sq. in. what load is borne by each staybolt if the pitch is 7 in.?

62. To what distance beyond the top of the upper row of tubes may the head conservatively be estimated to be supported by the tubes?

63. For what reason is the furnace of a vertical boiler made of light plate and stayed?

Questions Answered

Question.—35. What surfaces, owing to their shape, require no bracing to resist an internal pressure?

Answer.—Surfaces that form, or are part of, a cylinder, cone, or sphere.

Question.—36. Classify the stays used in bracing boilers?

Answer.—Direct stays, diagonal stays, and girder stays.

Question.—37. How are crown bars usually constructed?

Answer.—Two flat bars of wrought iron or steel are riveted or welded to blocks at each end, spreading being prevented by distance pieces placed between and riveted to the bars.

Question.—38. What means are adopted to give warning when a screwed staybolt breaks?

Answer.—A telltale hole is provided.

Question.—39. State how the crown sheets of combustion chambers of marine boilers are generally braced?

Answer.—The crown sheet is usually braced by crown bars and crown-bar bolts.

Question.—40. How are the tube-sheets of high pressure boilers braced?

Answer.—By stay-tubes.

Question.—41. How are stay-tubes fastened to the tube-sheets?

Answer.—By threading their enlarged ends, screwing them into threaded holes in the tube-sheets, and beading over the ends. Sometimes stay-tubes are further secured by nuts on the outside of the tube-sheet.

Question.—42. What is an Adamson ring-joint?

Answer.—A joint formed in a built-up furnace flue by flanging the sections and riveting them together with a finished ring between them.

Question.—43. What good feature is embodied in corrugated furnace flues?

Answer. — The corrugations permit free expansion and contraction.

Question.—44. Explain the purpose of boiler tubes; state by what process they are made and how they are designed.

Answer.—They are used for giving a large heating surface. Boiler tubes are made by lap welding or by the seamless drawing process and are designated by their outside diameters.

Question.—45. What process of manufacture produces the best steel boiler tubes?

Answer.—The seamless cold-drawing process.

Question.—46. State the purpose of a combustion chamber?

Answer.—It forms a space that provides for a thorough mixture of air with unconsumed gases of combustion, whereby complete combustion is aided.

HARDNESS AND WEAR

The Editor:—In your issue of May 20th, 1919, we find an article "Hardness and Wear" in which reference is made to abrasion of cast iron slide valves, seats, etc. As we are particularly interested in lubrication problems that are out of the beaten track, this article has made considerable impression upon us. However, recommendation for relieving this state of affairs is contained in a report of the committee on Superheated Locomotives of the American Railroad Association. They say:

"On the railroads using slide valves no change was made in the oiling or lubricating devices when bronze valves were used, but where the original cast iron valves were used some trouble with cutting the seats was experienced. The application of an additional system of graphite lubrication stopped the trouble."

The reasons behind this are not very hard to see, as the fine flake graphite fills up all the small pores, not only in the valve, but in the seat as well and then the movement is really one of one graphite surface over the other. In addition the very low co-efficient of friction of the graphited surfaces makes a very easy moving valve and one that will neither stick nor squeal.

We believe that the necessity of breaking the cast iron skin will be entirely overcome by the feeding of small quantities of fine flake graphite to the parts affected.

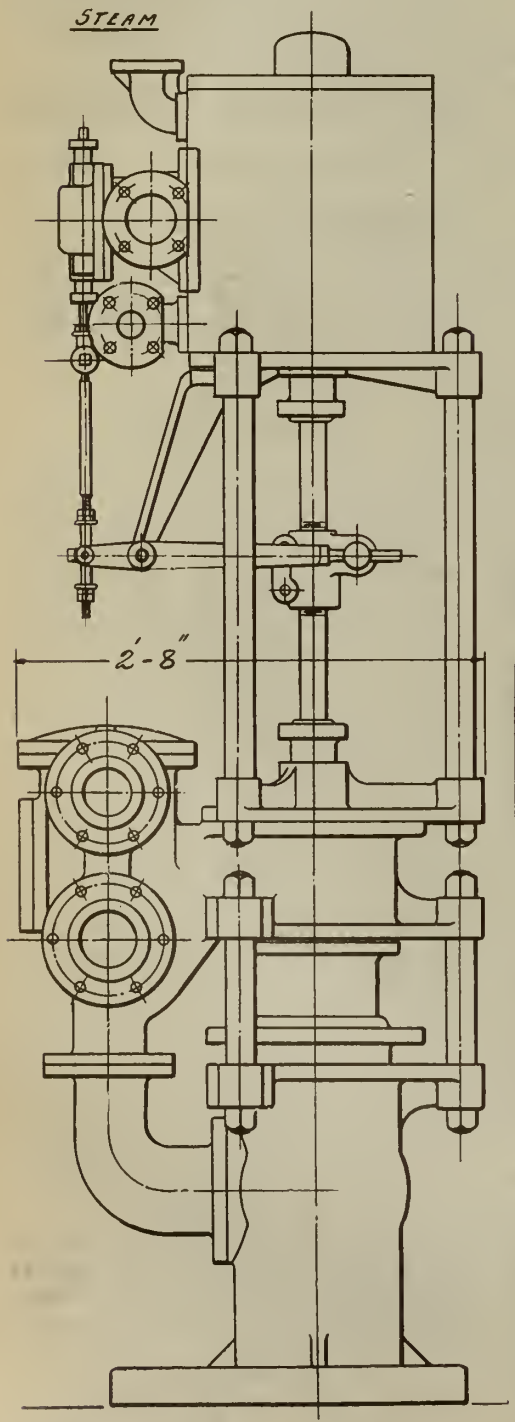
Very truly yours,
Joseph Dixon,
Crucible Company.

THE TOD-ATTWOOD RAM PUMP

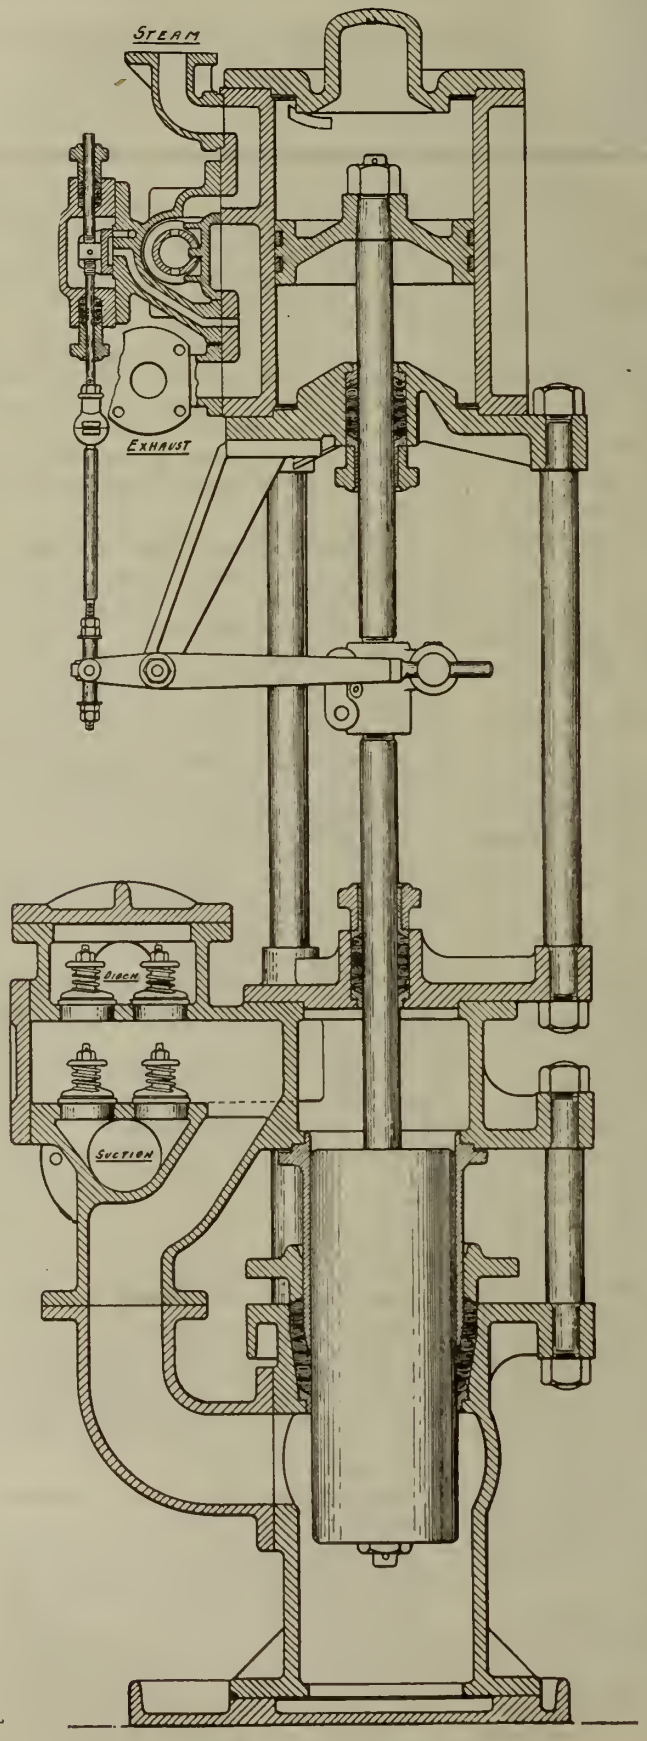
The vital part of a steam power plant is the boiler feed pump, and especially a marine steam plant, where the pump presents the only means of feeding the boiler. One of the latest developments in marine feed pump design is furnished by the Tod-Attwood vertical simplex pump, a description of which is given here.

A glance at the accompanying sectional elevation will at once reveal several departures from conventional design, all of which tend to make a smooth working and easily accessible pump.

The pump here described is the 11-inch by 8-inch by 12-inch size, which is designed to supply 1,250 h.p., at a piston speed of thirty feet per minute. This would require fifteen double strokes per minute, which is a very reasonable speed, conducive to long life. The steam piston is of the conical, or marine type, with two Ramsbottom rings. The valve arrangement for admitting steam is a combination of slide and piston valve, the slide valve being operated from a lever on the pump rod, and the motion of the slide giving steam to either end of the piston valve, which controls the admission to the cylinder. Unlike the majority of this style of valve, it is devoid of complications, the whole range of operations being taken care of by three main ports. The main valve chest is bolted on to the steam cylinder, and the slide valve chest is bolted on to the main chest, making access to either as convenient as possible. The ports in the cylinder bore are cut in such a manner that the piston automatically cushions itself at the end of the stroke, and so well has this feature been designed, that the suction connection can be broken with the pump under full working pressure, without any knocking at either end of the stroke. This is a remarkable claim, but it has been proved to the satisfaction of Lloyd's representatives.



OUTSIDE VIEW SHOWING CONNECTIONS



SECTION SHOWING CONSTRUCTION OF PUMP

At the water end of the pump, ample provision has been made to give easy access to suction and discharge valves. A hand hole door is provided on the suction valve box, and there is ample clearance between the top of valve studs and the discharge valve seats to enable a man to pass his hand through comfortably.

The ram is of gunmetal, as also is the cylinder liner, and the liner is arranged so as to be easily removable. There is only one packing gland which is arranged with ample working clearance round it, and the ram being water borne at all times, the wear on both liner and ram is but slight. The lower part of the chamber is made separate from the upper part, so that in the event of a break in either there is no need of a complete new water end. The steam end is supported on three rigid stanchions secured by nuts each end. All glands are bushed with gunmetal

Removing and Replacing Ceiling Motor Armatures

A Handy Rigging Which Enabled Heavy Armatures to be Handled With a Minimum of Labor and Time—Two Pair of Chain Blocks and Small Buggy the Means

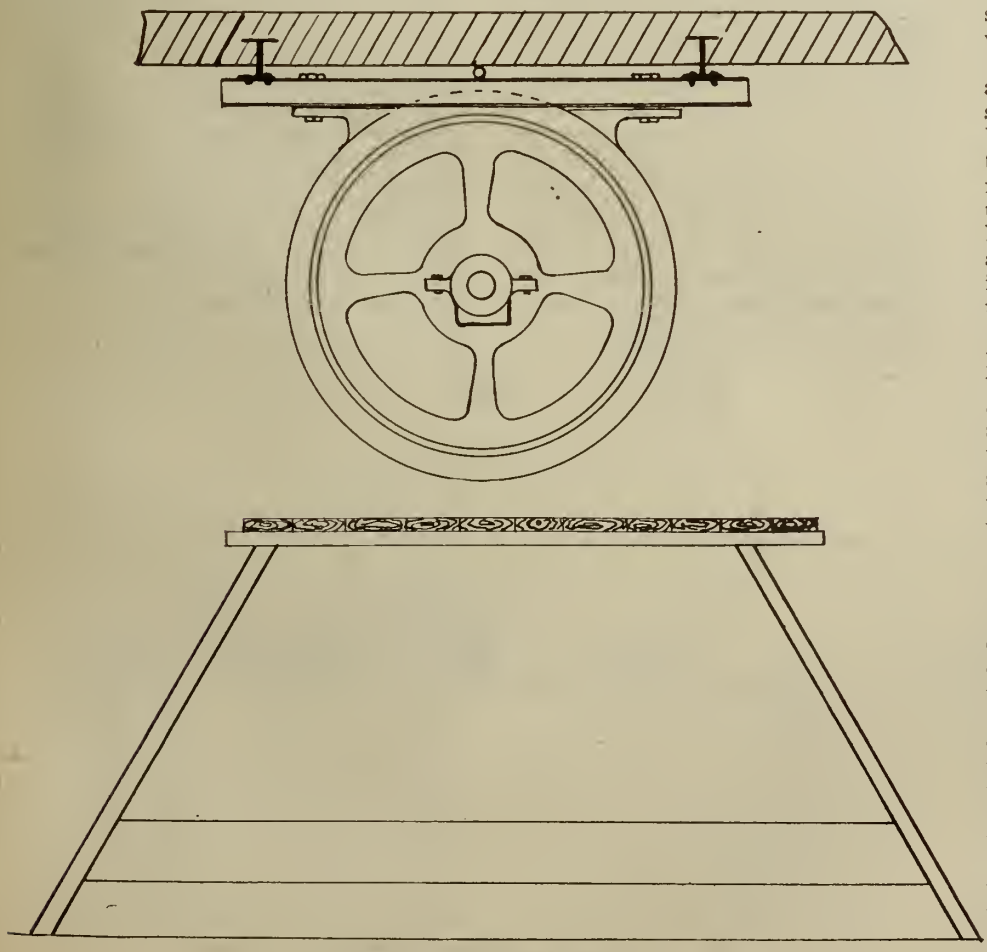
By T. H. FENNER, Associate Editor

IN manufacturing plants where the motors are suspended from the ceilings it is often necessary to remove an armature for repair and replace it by a spare one. The ease with which this work can be done depends on the familiarity of the millwright's crew with the job, and the gear available.

Direct-current motors of medium speeds and power have armatures weighing up to twelve hundred pounds, and require careful handling if they are to be moved without damage to men or property. This is especially the case where they are suspended from ten to fifteen feet in the air.

In one plant the writer has in mind a very good system had been evolved for doing this kind of work speedily and safely. The ceiling motors were about forty-five in number, running all the way from 1½ h.p. to 75 h.p., but the majority were 35 and 75 h.p.

Spare armatures were kept, and the rule was to remove an armature whenever it gave signs of becoming troublesome and replacing it with a spare. Sometimes of course an armature would burn out through various causes during the working hours. This would mean a certain number of machines being stopped, and in this case speedy replacement was a necessity.



SIDE VIEW OF THE MOTOR.

The motors were fastened to channel irons, which were in turn fastened to the I beams of the concrete floor above. These beams were made heavier than the ordinary floor beams in view of the extra weight. The line shaft was direct coupled to the motor shaft in most cases, and in some instances, where one motor drove two adjacent departments, each end of the motor shaft drove a line shaft. This of course made more work when an armature was to be removed.

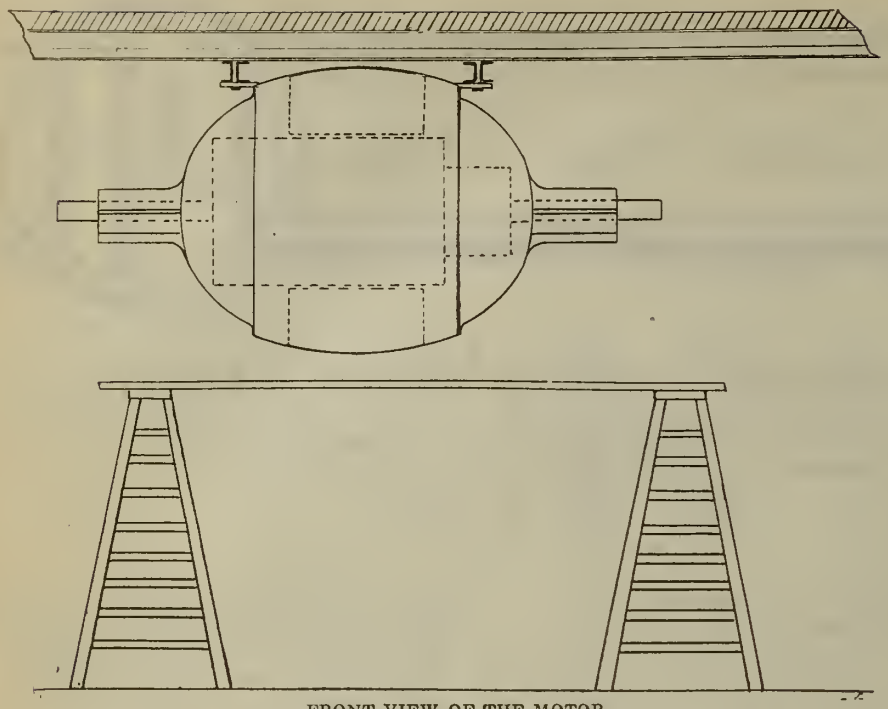
The hangers for the line shafts were about fifteen feet apart, the length of shafting being about seventeen feet. Where a heavy pulley was installed between the motor coupling and the first regular hanger, extra hangers would be used to take the weight of pulley and belt pull. The hangers were of the self-aligning type, and were bolted to three-inch wooden stringers, which were in turn fastened to the floor I beams.

In the millwright's store was kept a pair of strong, high trestles and enough two and three-inch planking to make a strong working platform. A supply of square blocking was also on hand and was kept for this particular work. A strong four-wheeled truck for moving the armatures from and to their place was also kept here.

The Method of Procedure.

The best way to describe the method employed is to follow the course of events from the time of receiving word of a burn-out till the repair is made and the motor running again.

The first step would of course be an examination by the electrician, and he would decide whether he could effect temporary repairs, or if the armature would have to be removed. If this was the case work would start immediately. While the electrician and his helper would disconnect the leads and remove the brushes from the commutator, the millwright's gang would hustle over their trestles, chain blocks, slings, etc.



FRONT VIEW OF THE MOTOR.

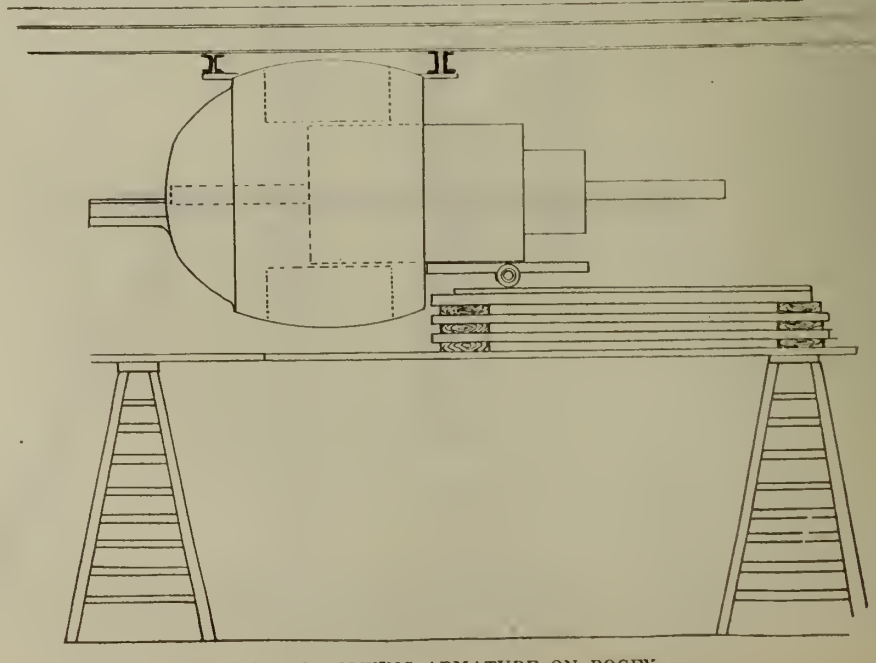
The first actual dismantling would be the removal of the length of shaft immediately adjoining the motor shaft. If there were no pulleys on this length the caps of the bearings would be removed and the length slid back over the hangers far enough to leave room for the armature to come back. If fitted with pulleys these would have to be removed first, though in some cases it would be feasible to lower the whole length of shaft, with hangers and pulleys intact. The shaft out of the way, the next step would be to remove the end housing. This was done by hitching the ½-ton chain blocks to a stringer placed on the ceiling and before slacking the cap bolts holding the housing, taking the weight of the armature on the chain block. The bolts are then taken out and the housing pulled back, the blocks being slacked out till the weight of the armature comes on the field magnets. The blocks are then hitched to the housing and the platform is opened up by removing two or three planks, and the housing lowered to the ground.

On the channel iron to which the motor is fastened, a length of shafting has been left for the purpose of holding the chain blocks. Two pairs of blocks are used, one at each end of the armature. The hook of the chain block at the end opposite to the commutator is passed down through the openings in the housing but is not used till the shaft is just leaving the bearing. It may not be needed at all, but it saves time to hang it up ready before moving the armature. The armature is moved out by the block at the commutator end by leading the block out of the perpendicular so that when tightened up it tends to straighten out, pulling the armature out with it.

By the time that the other end of the armature shaft is ready to leave the bearing another very useful little arrangement is brought into play. This is a small bogey mounted on two wheels at the centre and made with its platform curved to a radius approximately close to that of an armature. Blocking is made up on the working platform till the bogey can be set in just underneath the armature. If the armature is far enough out of the frame to rest on the bogey without tipping, the back pair of blocks will not be needed. Usually, however, the back chain block is tightened up sufficiently to prevent the armature dropping when the shaft comes out of the back bearing. Holding the weight on the two pair of blocks, the armature is worked out until it is fairly over the bogey, and then lowered. This done, the bogey is pulled back on the blocking till the armature is clear of the motor frame altogether. The use of this little carriage saves a great deal of time which would be otherwise used in making fluts and changing blocks. The next step is to lower the armature on to the working platform, which is done by taking a turn on each end of the shaft with the chain blocks and then removing the blocking. This gives more head room and the yoke for lifting can be put on. This is made up of a piece of 3-in. I beam with an eye in the centre for hooking on the blocks. Two pieces of ¾-in. round iron are screwed at each end and bent to a V shape, with the lower end widened out. These fit over the shaft of the armature, the screwed ends passing through the lower flange of the I beam and fastened with nuts. The 1-ton blocks can now be used for lowering. The weight is taken on the blocks, the platform opened up and the armature is lowered on to a truck moved in ready to receive it. This truck is then moved out and the spare armature moved in on its truck. The yoke is taken from the old armature and placed on the new, and it is heaved up. The platform is then replaced and the armature lowered on to it while the yoke is removed. The chain blocks are once more hitched at each end of the shaft, the armature raised up and the blocking put in again with the carriage on top. Working the armature into the frame is probably the most awkward part of the job as the shaft has to be entered fairly into the far end bearing and the oil rings held up carefully till the shaft has passed. The two pair of blocks are used when the carriage has reached its limit.

The armature replaced, the remaining parts of the work do not take long. If all goes well with connecting up the shafting, and couplings can be trued up reasonably quickly, three hours will see the completion of the whole job. This, to remove an armature weighing perhaps 1,000 pounds, and replace it with another, move and replace shafting, and rig platform and gear, is good work.

The number of men engaged on this work was usually five for the heavier motors. Of course handling the smaller ones was only a light job, and two to three men were sufficient.



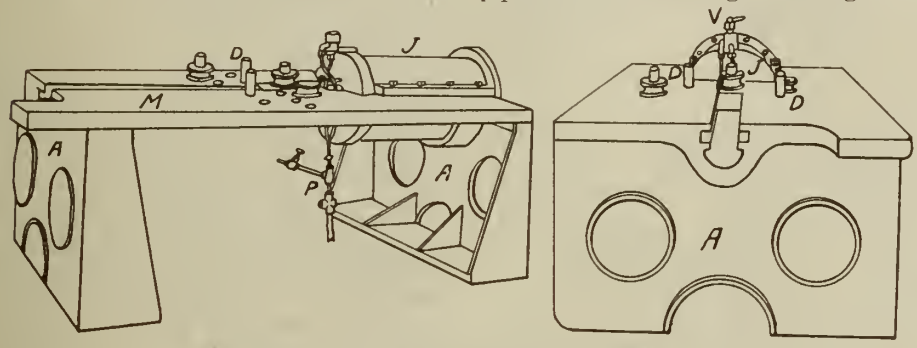
VIEW SHOWING ARMATURE ON BOGEY.

A PNEUMATICALLY OPERATED CONDUIT AND PIPE BENDER

By THOMAS A. CORBETT

Copyright, all rights reserved by the author

A Pneumatically-Operated Pressure Bender (Fig. 1) designed and used by the Wabash Shops at Decatur, Illinois, has proven in as a most useful machine. In any industrial plant or large contractor's shop where much conduit or pipe is bent a tool of this character will soon pay for itself by virtue of the economies in time and material which it effects. Saving in time results because the machine forms bends more quickly than they can be bent manually. Furthermore, one man can operate the pneumatic bender, whereas two may be required for bending by hand tubes of the larger diameters. Economy in material results because, after the rolls have once been set, the bends produced by the machine are of a uniform contour which cannot be reproduced with hand bending. Hence, little or no material is lost through spoilage. The Southern Pacific Railroad Company has a pneumatic conduit bender in its shops at West Alameda, Calif., and the Westinghouse Electric & Manufacturing Company has one in its East Pittsburg Works. Both of these machines are used for bending conduit electric car and locomotive wiring and for wiring around the plants. There are two duplicates of that illustrated, in the Wabash Shops. Doubtless a number of others, designed and constructed in the plants where they are operating, are in use.



FIGS. 1 AND 2.—ASSEMBLY OF BENDER.

The piece of conduit to be bent is placed on the bending table, M, so that it lies across the T-slot (Fig. 2) in the grooves of two of the rolls. Then the operator, by throwing the throttle of the air control valve, V, admits air to the rear end of the air cylinder, J. This forces the third grooved roll, carried on the crosshead of the piston rod, against the conduit. Thereby the tube is bent to the desired contour. The pipe having been bent sufficiently, the throttle of the control valve is reversed, which returns the piston to its extreme position where it is ready for another operation. It requires only about one half minute—the time consumed by the piston in moving the length of its stroke—to make a bend with the machine.

Rolls of Various External Diameters and Having Grooves of Different Sizes are Provided for tubes of different diameters and for forming bends of different radii. In Figs. 3 to 6, inclusive, are indicated the mechanical details. The extension of the top plate at X and X (Fig. 3) is to provide for the clamping on of pipe vises for threading the fitting. The piston rod, H, (Fig. 4) is held in the piston head, L (Fig. 5) by being screwed in against a shoulder, which is not shown in the details. The end of the piston rod is then headed over. Cylinder rings of leather are used on the piston head, as shown at III in Figure 5. Steel-wire spreaders hold these leathers out against the sides of the cylinder. The ¾-in air supply pipes from the control valve, V, enter each of the cylinder heads. The air pressure used is 100 lb. per sq. in. In the stuffing box in the cylinder, J, for which the gland of Fig. 6 is used, Garlock round packing is employed.

Note that pins, D and G (Fig. 4) of two diameters are employed for the accommodation of the two sizes of stationary rolls. The lower ends of these pins are tapered to fit correspondingly tapered holes shown in the top plate in Fig. 3. The V block, B, held by the clamp C (detail in Fig. 4 and shown in position in Fig. 3) is used for holding a length of conduit for straightening or for bending. A movable roll held on the crosshead pin E is forced up against the pipe, thus gripping it in the V-block of B.

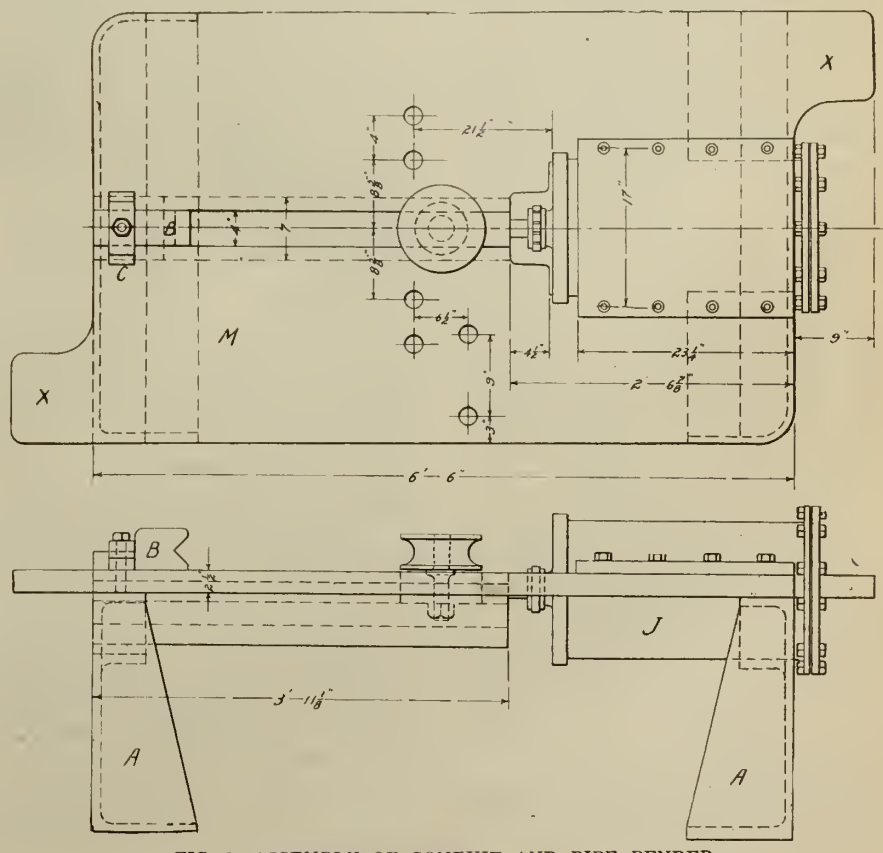


FIG. 3—ASSEMBLY OF CONDUIT AND PIPE BENDER.

FASTENING ANCHOR BOLTS

By Hal B. Beecher

Some very interesting information is given in the letter by Terrell Croft on page 291 of POWER HOUSE of July 5. What he states in reference to a foundation bolt being set in cement 30 times its diameter may be quite true, nevertheless I would advise builders of foundations to stick to the old safe plan and place some kind of a hold-back on the end. A right angle bend on the end will answer. No thread, nut, washer or plate is necessary as it is a practical impossibility to pull such a bent bolt out of a set cement foundation.

If, in following out Mr. Croft's idea, a very small amount of oil might be left on the bolt, this would be fatal to the effective adhesion of the cement to the rod, or the rod or bolt might be slightly rusty, which might be as bad as the oil; another point in placing foundation bolts is this: Whenever possible the bolts should have an outside casing at least

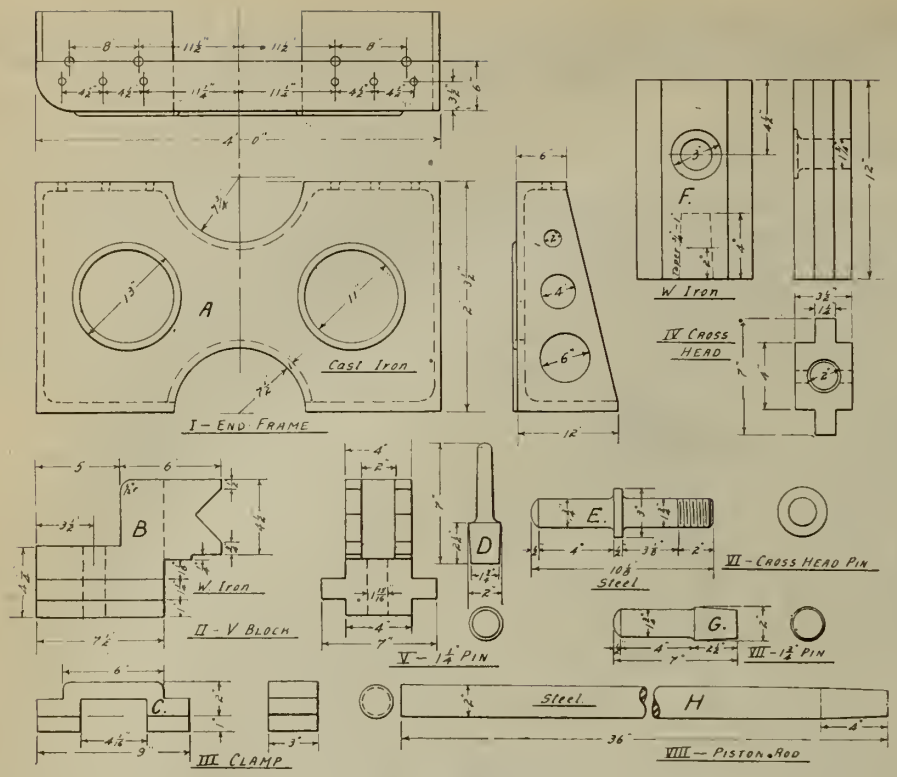

FIG. 4—DETAILS.

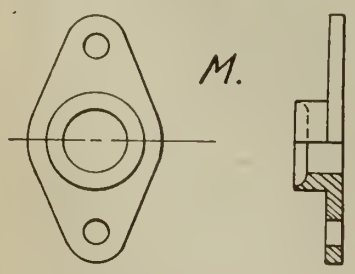
double the diameters of the bolt, such as a piece of iron pipe, and a fairly large piece of iron plate at the bottom. A thick nut should be used on the bottom of the bolt, the thread on the rod being such that it makes a snug but not tight fit into the nut. With such a layout it is possible at any time to remove the bolt or bolts if it is necessary to move the machine for repairs, or other reason. With the bolts removed the machine can be moved on low rollers with ease. With heavy machines with high bases this point is worth considering as the cement will have set around the nuts holding them in place; it is an easy matter to replace the bolts. In some cases a recess is formed below



GLAND DETAIL.

the bolt head so that by removing the top nut the bolt can be lowered until the top of the bolt is level with the top of the foundation; when this plan is used a small hole is drilled and threaded on top of the bolt so that a small rod can be screwed into the bolt to lift it up when the machine is in place. Much more might be written on this subject but one thing I wish to repeat: do not adopt Mr. Croft's plan, for it looks to me that a headless bolt set in cement might possibly be loosened into its bed if the bolts were subject to sharp and constant vibrations, which would have the same effect all through the bolt. I imagine I could loosen such a bolt so that it could be pulled out without breaking, by tapping or striking said bolt for some time close to the cement, using a hammer or other tool.

ANTI-FREEZE FOR THE RADIATORS

A friend was telling me that a few pounds of chloride of magnesium added to the water in a house heating system will prevent the water in the pipes, radiators and boiler from freezing, should the fire go out or the house be left idle, and that the chloride will do no injury to the pipes. I thought I would pass this information along, as it is a mighty fine thing to know, if it is true. This mixture should also make a good anti-freeze liquid for auto radiators.

By J. E. M.

Editor's Note: Calcium chloride lime is well known as a refrigerating medium. Certain anti-freeze compounds on the market for motor radiators have as their basis nothing more nor less than calcium chloride.

THE TOD-ATWOOD RAM PUMP

Continued from page 346

bushings, and the workmanship throughout is of the best. The pump has earned the seal of approval of Lloyd's surveyors here, and is at present under examination by the Bureau Veritas. The pump is manufactured by the G. H. Tod Co., Ltd., Toronto, who also manufacture a line of stationary pumps embodying some of the features of the pump described. The overall dimensions of the pump shown are 7 feet 9 inches high by 2 feet 8 inches wide. The floor space is 24 inches by 32 inches.

Electric current is available to most people, but it is not always apparent whether it is direct or alternating, 110 or 220 volts. A new pocket instrument, 4 inches long, 2 inches high, and 1½ inches wide, has a dial at each end in which the letters "A. C." or "D. C." appear, as the case may be, when the flexible cords are connected to the circuit. The voltage is indicated in the same manner. Provision is made for connecting to any kind of terminal, a plug being provided into which the posts on the wire-ends fit, for lamp-socket testing.

* * *

Word comes from the north-east coast of England of a vessel that has been designed to meet the need of an unsinkable ship. To accomplish this end the bridge of the ship is made watertight, and is made large enough to accommodate all the people and valuables on board. It is not made integral with the ship, but is attached thereto with easily-detached fastenings, and in the event of the hull being mined or torpedoed, the bridge will have enough buoyancy to float and sustain the weight of the immersed hull. The crew and passengers can remain in the bridge until taken off or towed into safety. If the hull through very bad weather becomes a danger to the bridge it can be released and allowed to sink, leaving the bridge afloat.

* * *

Stamping, drawing, and general press work on cupro-nickel can be accomplished as easily as with brass, according to the "Metal Industry." The metal can be more drastically treated, and stands greater reduction than brass, although more power is required than for working most alloys. Annealing cupro-nickel articles between operations is not advisable, chiefly on account of the great tendency toward fire-cracking and the production of excessive scale, which is very difficult to remove, and which, unless entirely eliminated, will ruin punches and dies.

* * *

Zinc water pipes which come in contact with mortar containing gypsum become in a relatively short time corroded and eaten through. Where the surface is wetted and quickly dried a protective coating of zinc oxide is formed, but where the contact with running rainwater is prolonged, such as in the case of roofing plates and gutters, energetic action must be reckoned with. According to "Building News," the most active agent of destruction is sulphate of lime. Zinc is energetically attacked by mortar containing gypsum sand, but only feebly by mortar containing limestone sand alone, or with an addition of gypsum. Lead, on the other hand, is energetically attacked by limestone alone and with an addition of gypsum, but only feebly by gypsum sand mortar. Both metals are strongly attacked by pure cement, but the destructive action is lessened by the addition of sand. Hence zinc should be put in contact only with limestone—carbonate—mortar, and lead only with gypsum—sulphate.

To Build Mammoth Plant

The Lunkenheimer Company, Cincinnati, Ohio, manufacturers of valves and engineering appliances, has announced its intention to greatly increase and improve its manufacturing facilities by building a complete new plant. The site selected for the undertaking comprises about seventy acres of land in Carthage, a suburb of the city of Cincinnati, directly on the Toledo Division of the Baltimore and Ohio Southwestern Railroad. The location selected is not far distant from the centre of the city, is in the heart of one of the manufacturing sections of the city, where labor is plentiful and facilities for the handling of incoming and outgoing freight is ideal.

Buildings will be of the one, two, three storey types, of steel and concrete construction, and there will be provided all modern devices for the manufacture, handling, and transportation of raw materials, part finished and finished products. The undertaking will represent an outlay of approximately $2,000,000.

The welfare of the employees has been given special consideration. A piece of land about eight acres, lying directly opposite the land upon which the main plant is to be located, has been reserved as a recreation centre, upon which will be erected an assembly hall, club rooms, base ball grounds, tennis courts, swimming pool, etc. Upon this site will also be erected a dining room capable of accommodating one thousand employees at one time.

Arrangements are being made so that there will be no interruption to the business of the company while the building operations are in progress, nor while the task of moving into the new plant is under way.

"We Welcome Fair Competition" is the title of a circular just issued by the Portable Machinery Co., Passaic, N.J., manufacturers of the Scoop Conveyor. It briefly describes how one concern has copied and is trying to market an imitation of the Scoop Conveyor. As there is suit now pending for infringement of rights, the circular warns possible customers of portable conveyors against purchasing the imitation.

The Combustion Engineering Corporation, New York, have issued a new catalogue on their "Grieve Grates." This publication shows in an interesting manner, both as to text and cuts, the detail and operation of the grate.

The Vulcan Soot Cleaner Co., Du Bois, Pa., have issued a publication entitled: "Six Vital Features of Vulcan Superiority." As indicated in the title the various excellent features of design of this soot cleaner are dealt with in a thorough manner.

S. F. Bowser & Company, Inc., Fort Wayne, Ind., have issued two new publications on "Systems for Oil Economy and Efficiency," and "Handsome Returns to Yourself." These pamphlets deal with the economies to be secured in providing proper methods of handling oil in industrial processes and for lubrication.

Newfoundland Imports Free. — The last restrictions on imports into Newfoundland have now been removed, by flour being restored to pre-war conditions.

Substation Expands.—The Toronto Hydro-Electric Commission has purchased the property at 27 and 29 Nelson Street, for the purpose of extending the substation at Duncan Street.

Saw Mill Burns.—The saw mill of Mr. Musclow, situated at Musclow, North Hastings, was completely destroyed by fire recently. The loss is a total one and is not covered by insurance.

Algoma Steel to Extend—The Algoma Steel Co. will spend several hundred thousand dollars in making extensions to their mills, to enable them to manufacture structural steel up to 32 inches.

English Firm For Hamilton.—The firm of Perrits & Spencer, Bury, England, will build a factory in Hamilton at an approximate cost of $600,000. W. J. Westaway has been appointed engineer for the building.

New Smelting Plant.—The forthcoming industrial congress at Calgary will consider the establishment of a smelting plant near that city, the new process of smelting by electricity to be employed. Considerable interest is being displayed already.

New Industry for Hamilton. — The Carr Fastener Company of Boston, Mass., are to open a factory in Hamilton. This firm are said to be the largest manufacturers of fasteners in the world. The Hamilton branch will be known as the Canadian Carr Fastener Company, and will be probably capitalized at $250,000. Two and one-half acres of land on Gage avenue have been purchased.

Municipal Power for Port. Colborne.—Port Colborne decided by a vote of 141 majority to purchase the distribution system of the Ontario Power Company in Port Colborne.

The Andian National Corporation, Ltd., has been incorporated with a capital stock of $1,000,000 in 10,000 shares of $100 each. The object of the company will be to search for minerals, oil, gas, etc. The head office of the company will be in Ottawa.

Corporal William A. Nugent, who served during the war in Company I, 21st Engineers, has returned from France and resumed his duties with the Independent Pneumatic Tool Co. as traveling representative. He has been assigned to his old territory in Indiana.

The proposed extension of the water supplies to Moose Jaw, Sask., Con., will entail laying a pipe line about 70 miles long. The pipe will be of wood and 24 in. in diameter. The relative costs of wood, steel, and cast iron pipe for the work are in the proportion of 2.3, 5.7 and 10.5.

Electrifying Montreal Harbor.—The Montreal Harbor Commissioners have awarded contracts for material required in the electrification of the railways on the wharves. Work will be started as soon as material is available. A generator set will have to be installed, the rails bonded and poles and wires erected.

Heavy Shot at Chippewa.—A dynamite charge that cost between $4,000 and $5,000 took place at Chippewa recently. The amount of dynamite used in the blast was in the neighborhood of ten tons. It was used in opening up a large section of rock in the forebay of the new development canal above Queenston.

A Fortune in Oil.—Mr. Kenneth Johnston, a former Sarnian, but now of Buffalo, is the inventor of a lubricating grease, which has been taken up by one of the largest oil companies in the United States. The sum paid to Mr. Johnson for his invention is said to be $600,000. He is a veteran of the South African war.

WM. B. SCAIFE & SONS CO. PITTSBURGH, PA.

The Nova Scotia Government is to create a hydro-electric commission similar to that in Ontario. Two bills, one to authorize the development of water power and the other to lay down regulations covering water and water courses, have been introduced in the Provincial Legislature.

The Battery Engineering and Supply Co., Ltd., with head offices in Ottawa, has been incorporated with a capital stock of $50,000, divided into 500 shares of $100 each. The company will manufacture all kinds of electrical appliances and automobile engines.

The Continental Storage Battery Co., Ltd., has been incorporated with a capital stock of $50,000, divided into 500 shares of $100 each, the head office being in Ottawa. The object of the company will be to make and sell batteries, and deal in automobiles and supplies generally.

Going Ahead.—The R. McDougall Co., Ltd., Galt, were not seriously inconvenienced by the fire which took place in their plant recently. The machine shop and foundry were uninjured, and the patterns that were burned or injured have been largely replaced. Their deliveries on their usual lines have not been interfered with.

To Relieve Congestion.—The British authorities, in an endeavor to relieve the congestion at the leading shipping ports, are introducing a new rule. All heavy cargoes consigned through ports where congestion is being experienced to destinations that can be more easily served through other ports will be transferred to coastwise steamers at once.

Contract Let.—The General Motors of Canada, Ltd., has awarded the general contract for a factory at Oshawa, Ont., to cost $1,000,000 to the Canadian Stewart Co., foot of Cherry street, Toronto. It will consist of an assembling building, four stories, 40 x 80 ft., of reinforced concrete; shipping building, 80 x 200 ft.; storage building, four stories, 80 x 800 ft.; enameling building, 80 x 300 ft., three stories.

New Cyanide Plant for Canada.—The Cassel Cyanide Company, Ltd., of Glasgow, Scotland, are about to incorporate a Canadian branch of their company. This is on the recommendation of their manager, Mr. Neill, after making one of his periodical tours of Canada and Mexico. He was very favorably impressed with the mineral resources of Northern Ontario and the industrial possibilities of the country generally. The board of the Canadian company will have three members from the Glasgow board, and Mr. Neill will divide his time between the Canadian firm and the parent company.

Increasing Yard Area.—The large farm of A. Weaver, on the Niagara River frontier, nine miles from the International Bridge, has been secured by a party of Toronto realty dealers. It is understood that the ground will be used for extending the yard holdings of the Canadian Niagara Bridge Company.

Veteran Contractors.—A firm of contractors has recently been formed in Vancouver, the members of which have seen service in France on railway work. They have taken a contract for one and a half miles on the Copper Mountain Railroad near Princeton. They will, as far as possible, employ none but returned men, and the wages paid will be up to the prevailing standard. To those men who stay on the work till completion a percentage of the profits will be given.

To Try New Boilers.—In order to try out the Spencer heating boilers equipped with self-feeding furnaces, which have been successful in Hamilton schools, the Board of Education of Toronto departed from their usual rule of accepting the lowest tender. The difference in the bids was as follows: Tubular boilers, $12,300; brickwork, $6,100. Spencer boilers, $15,500; brickwork, $7,375. The installation in Toronto will be in Howard Park School.

Newmarket Boiler Explosion.—At the inquest into the boiler explosion which caused the death of five persons recently in Newmarket, evidence was given to the effect that the water used in supplying the boiler was high in sodium carbonate. The analysis of the water coincided with that of the water in other districts where the embrittlement of plates by the action of sodium hydroxide has occurred. The water is from an artesian well on the premises. The town supply and the Office Specialty Supply Co. supply were found to be free from sodium carbonate.

Sells Buffalo Plant.—The Russell Motor Car Company has sold its Buffalo plant, which was an important subsidiary during its operations on war contracts. It is said that the sale is an advantageous one, realizing more than the company put into it. It is reported that the company is having a successful year, and will close its fiscal year on July 31, with a good record, though somewhat less earnings than in the bumper period before the close of the war.

Mr. W. B. Roberts, who has just returned from England, where he held the rank of Lieut. Commander (Engr.) in the Royal Navy, has been appointed chief inspector for Saskatchewan and Alberta, for the General Accident Insurance Co., boiler department. Mr. Roberts, before going overseas, represented the company in that territory for about two years. He was connected with the Manchester Steam Users' Association for a period of five years, where his opportunities to obtain expert knowledge of boiler questions was unlimited. Besides his naval experience, he was in the mercantile marine for some years, and holds the extra first-class certificate of the British B. of T. He should be a great acquisition to the engineering fraternity of the prairie provinces.

SPLENDID OPPORTUNITY FOR ENGINEERING SALESMEN

Canadian War Inventions.—There is a department at Argyll House, London, which has been instituted to deal with Canadian war inventions. A large number of devices have been submitted, of which a fair proportion were found to be of practical utility. Chief among these may be mentioned the following: Improvement to gas masks, of which about three million were manufactured, by Lieut. C. Rosling, C.E.; Lewis magazine loader and improvements to Colt machine gun, invented by Major H. R. Northover, M.C.O.B.E., both of which were used, and a bomb dropper invented by Lieut. Col. W. F. Kemp, D.S.O. The inventions cover appliances all the way from a combination turf cutter and conveyer to an auxiliary field kitchen.

The Cost of Coal.—The wild rumors that coal will jump in price as much as $5 to $6 a ton, and a famine develop during the winter, are discounted by Canadian coal dealers, who have been looking into the situation in the States. There will be a shortage, it is thought, and probably a small rise in prices, but nothing like the rise that has been freely prophesied. If people get panicky and all rush to buy coal at the one time there will be a fictitious situation created which will tend to elevate prices. Many of the Italian laborers are returning to Italy, which is creating a shortage of labor, naturally affecting the output. There will be enough coal available to face a normal winter is the consensus of opinion.

The Alien Getting Even.—The many aliens of supposedly Austrian nationality, but really Slavs and Croats, who have been working in the anthracite mines, are getting out of the country as fast as they can. Forty-two thousand have already gone, and as fast as steamer space becomes available, more are going. These men, who were far from being in sympathy with Austria during the war, resented the attitude displayed by many Canadians to them, and as a result of their being so anxious to get back to their own countries, there is a grave danger of many of the people who vilified them being cold this winter. The production from the mines, where central Canada gets her anthracite coal was, up till the end of June, only 38,000,000 tons, ten millions less than for the corresponding period of 1918.

The Coal Situation in B. C.—Sir Robert Borden sent a telegram to the mayor of Sydney Mines, which was read at a labor meeting recently. The Premier stated that the Canadian National Railways were taking more coal from Nova Scotia this year than last, and had divided their orders between sixteen different mines. He pointed out the handicap that Nova Scotia was under owing to the shortage of ship tonnage. He stated that the Canadian National now had a stock of coal on hand good for seventeen weeks and were adding to their stock daily. Mr. R. H. Butts denounced the leaders of the United Mine Workers locally as demagogues and agitators. Mr. McLachlan, addressing the meeting, was not disposed to accept the Premier's explanation and thought that much of the present unrest was due to the Government's attitude towards labor. He thought that United States coal should be shut out of Canada altogether.

New Company Starts.—Statement was issued at Toronto City Hall, that the Nukol Company had taken a lease of the property formerly occupied by Toronto Shipbuilding Company. The lease, which was issued by the Harbor Commissioners, is for 21 years. It occupies some 2½ to 3 acres. The company is importing machinery from Belgium, and will start operations in making Nukol as soon as it is installed.

The Jeffrey Manufacturing Company, Jeffrey, Columbus, Ohio, have issued catalogue number 210 on the Jeffrey Pivoted Bucket Carrier, well illustrated with engravings and forming an unusually complete treatise on the subject of conveying. In addition to the many illustrations showing typical installations, line drawings are given which show practically all the dimensions necessary for the complete installation of this type of mechanical conveyer.

INCORPORATIONS

The Canada Stoker Co., Ltd., has been incorporated with a capital stock of $40,000, divided into 400 shares of $100 each, the head office to be in Galt, Ont. The company will carry on a general business.

The Phoenix Construction Co. has been incorporated with a capital stock $100,000 in 1,000 shares of $100 each, and head offices in Montreal. The company will carry on business as manufacturers of metal products, etc.

The London Clay Products Ltd. has been incorporated with a capital stock of of $50,000 in 500 shares of $100 each, the head offices to be in London. The company will manufacture all kinds of sewage pipe, tile, etc.

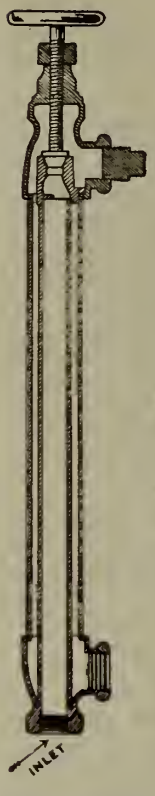
The Armstrong Cork and Insulation Co. have issued two booklets on "Nonpareil Corkboard Insulation for Cold Storage Rooms" and "Saving 63 Per Cent. of the Drinking Water Expense." As indicated by the titles these publications deal with the important subject of economy in refrigeration.

Lead poisoning is being investigated these days, because of its widespread existence in various industries. The Working Conditions Service, Department of Labor, has prepared, as a guide to industrial physicians, a schedule for the physical examination of lead workers, in which provision has been made for covering not only the typical manifestations of lead poisoning but also for bringing out the previous history of the worker, to determine whether hazards in other industries may have had an adverse effect upon the health. This schedule has been forwarded to districts in which lead poisoning in the pottery industry has appeared.

The LONG

PATENT

STEAM TRAP



Saves Coal

The Long (Patented) Steam Trap conserves fuel by stopping steam wastage.

Most simple and effective Steam Trap you can install in your plant. **Has only one Moveable part.**

The Long Trap is open at the start and cannot become air bound. Never freezes. Works against 1 and 200 pounds pressure. Can be installed in any position.

Write us and we will send you the full story of its efficiency. 'Twill save you worry, time and money.

NON-CORROSIVE
CYLINDER OIL
MANUFACTURED ONLY BY
E. H. KELLOGG & CO.
NOS. 242 TO 244 SOUTH ST. NEW YORK, U.S.A.
FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done—give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

E. H. KELLOGG & CO.,
New York, U.S.A.

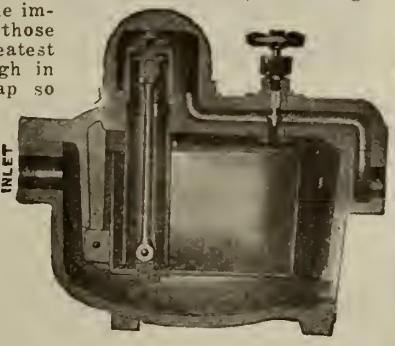
KIELEY

IMPROVED HIGH AND LOW PRESSURE

STEAM TRAP

For General Service

No power plant should be without a dependable steam trap. It is the great economizer of fuel and promoter of power plant efficiency. The KIELEY Improved Trap is the latest development in the art of steam trap construction, and is suitable for all service, either high or low pressure. The important parts and those subjected to greatest wear are placed high in the top of the trap so that by removing two nuts and the small cap all parts are easily accessible and removed for repairs — no breaking of connections necessary, neither do you have to remove the cover. Seats and discs are of best metal, absolutely non-corrosive; for exceptionally severe service seats and discs are constructed of nickel or monel metal, and the bodies of cast iron. Kieley traps never leak when in service—our water seal assures you this.



Leaky, unreliable steam traps are expensive. Adopt the KIELEY and be certain of efficient, economical service.

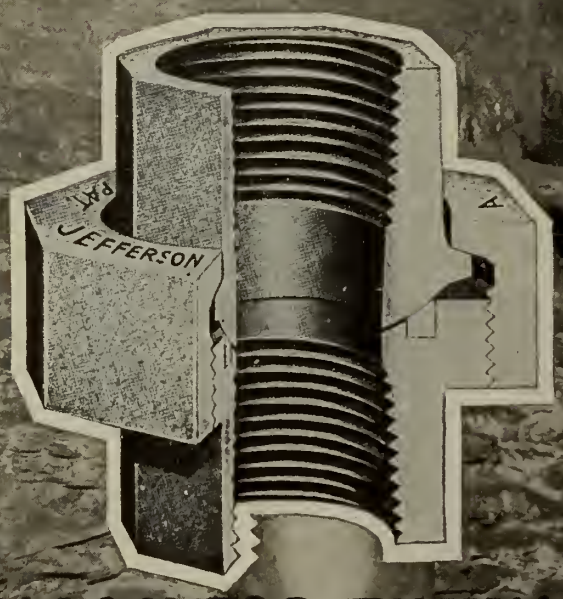
JEFFERSON



"LOOK FOR THE NAME ON THE NUT"

Underground

Take a trip underground—listen to the music of the pumps—"CHUG, CHUG, CHUG" — twenty-four hours a day, and you'll realize the importance of dependable unions. The failure of a single union might cause serious consequences involving loss of life and heavy damages.

JEFFERSON UNIONS will render perfect service as long as the pipe line holds out. Once you put a JEFFERSON on the line, you can say "Good-bye" forever to pipe line troubles.

Insist on genuine JEFFERSON Unions—the name on the nut protects you from the "Just-as-good" variety.

Talk over unions with your jobber. He has JEFFERSONS in stock and can tell you why JEFFERSONS always make good.

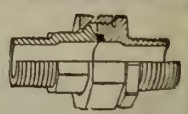
Write for our catalog "UNIONS"

Jefferson Union Co.

Lexington, Mass.

Male and Female Union. Takes the place of an all-female union and a nipple. Makes a short connection.

Union Elbow, all female. Takes the place of a straight union, nipple and an elbow. Also made male and female.



All Male Union. Saves two pipe joints between two female threaded parts.

Cranes for all Purposes

LINK-BELT Locomotive Cranes are rendering highly efficient service in leading industries throughout Canada.

They are handling ore at foundries. Handling steel at fabricating plants. Handling small parts with electric magnets at factories. Handling coal and ashes at power plants. Handling steel in ship yards—in fact wherever heavy parts or assembled products are to be handled economically and with dispatch, there you'll find Link-Belt Locomotive Cranes on the job.

And in each case you'll find them rendering a highly satisfactory service. For back of Link-Belt Cranes is a great engineering organization. Each crane is of the highest standard throughout—the same high standard which has long characterized Link-Belt products and made the name Link-Belt a guarantee of quality and efficiency.

Send for our Crane Book No. 370. Gives complete details.

A SOLID ONE-PIECE, JOINTLESS LEAKLESS LINING

Your Boiler Furnace Linings--How Often Do You Repair Them?

During the year how many times must you cut out your boilers to completely reline the furnaces?

Of course the life of a boiler furnace lining depends a whole lot on the service, but have you ever considered what it would mean in dollars and cents if you could reduce that number of repairs or renewals?

And it can be reduced at least 3 to 1 under ordinary load conditions.

It's the one-piece, monolithic boiler furnace lining made of Betson's Plastic Fire Brick that makes this possible. What's more—a Betson lining becomes harder and stronger with service.

BETSON'S
REG. U.S. TRADE MARK PLASTIC FIRE BRICK PAT. OFF

Back by a Service Record of 20 Years

In those plants where economy is a reality, and where continuous operation is all important—there you will find that the Chief relies on Betson's.

Our illustrated booklet tells how anyone can make a durable furnace lining. Just ask for it.

International Chemical Co.
44 Lombard Street
TORONTO, ONT., CANADA

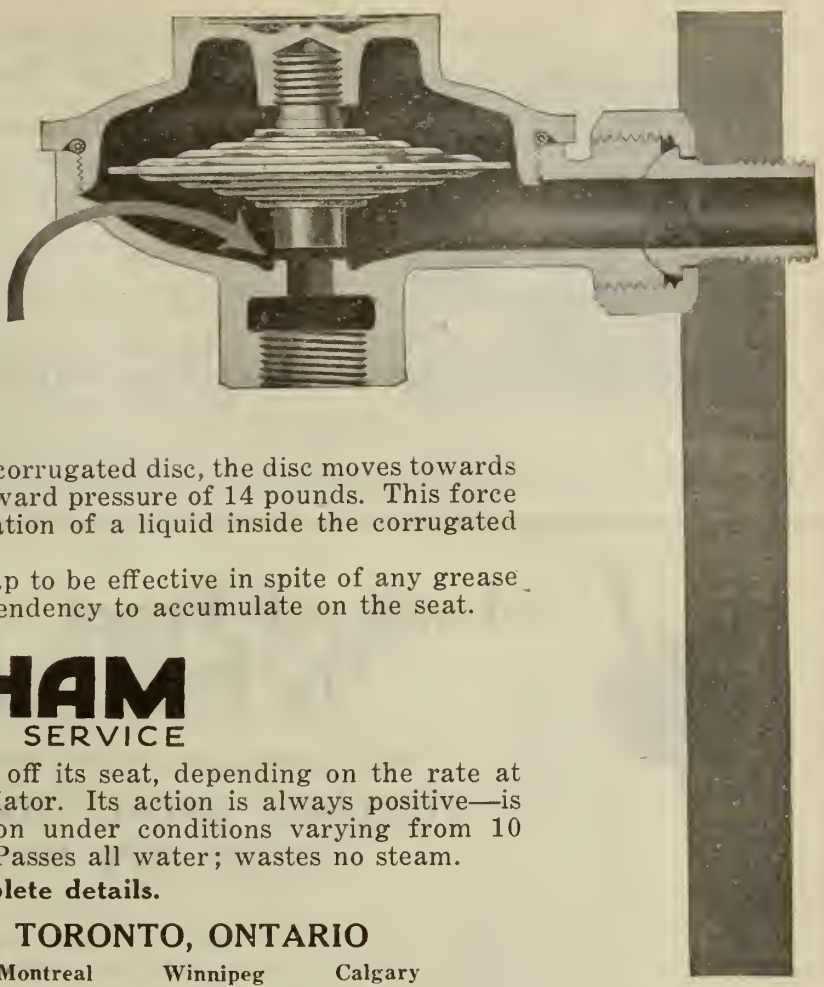
14 Lbs. Pressure downward



AS soon as steam strikes the sensitive corrugated disc, the disc moves towards its seat and exerts a maximum downward pressure of 14 pounds. This force is exerted uniformly by the vaporization of a liquid inside the corrugated disc.

This downward pressure causes the trap to be effective in spite of any grease and foreign matter which might have a tendency to accumulate on the seat.

The DUNHAM HEATING SERVICE

In action, the disc is alternately on and off its seat, depending on the rate at which the steam is condensed in the radiator. Its action is always positive—is never sluggish—and can be depended on under conditions varying from 10 pound pressure to 15 inches of vacuum. Passes all water; wastes no steam.

Write for complete details.

Settling the Packing Question

More experimenting has been done with packing than with any other power plant supply—and most of it has been done at the expense of the users. The packing question has been such an ever present problem with most engineers that they have been willing to try almost anything that promised relief. And it is easy to make packing — *of a sort.* Consequently there are dozens of brands — good, bad and indifferent. We do not claim that

VULCABESTON
RED FIBRE SHEET PACKING

is the *only* good packing. But we do claim—and stand ready to prove—that Vulcabeston is the equal of any packing made, at any price, and that it has one most important advantage: Where other packings are satisfactory for one or two kinds of service *only*, Vulcabeston is equally good for *all* kinds of service. It is the universal packing. That is why Vulcabeston settles the packing question once and for all.

The Secret of the Strikes

Most Canadians are asking "What is the cause of the 'Great Unrest' "? Is it the fault of labor—or of capital?—or is it the result of German propaganda? Do you know of the real reason for the labor disturbances in Canada, and elsewhere? Are YOU thoroughly familiar with the ins-and-outs of the plans which threaten a world-wide "tie-up?" This is something that should be understood by every Canadian. And every Canadian should read "The Secret of the Strikes," by Lieut.-Colonel J. B. Maclean in the August issue of MacLean's Magazine. It is brimful of startling and authoritative information regarding this great problem. Read it carefully. It starts on page 33, August MacLean's.

"The Lecturer At Large"

Stephen Leacock is one of the continent's greatest humorists. "The Lecturer at Large" is one of the best humorous sketches that he has written. It is made up of what he terms "a few painful reminiscences of the platform" in the course of his lecturing up and down Canada. Get your family around you and read the sketch aloud—it's a rare treat.

Other Big Features

"A Party in the Making." By J. K. Munro. Illustrated by William Casey. An article on the political situation, giving a great deal of inside information with reference to recent developments at Ottawa.

"Solving the Problem of the Arctic." By Vilhjalmur Stefansson. The fifth instalment of his story of the five years' explorations that he conducted for the Dominion of Canada.

"The Unspoiled Country." By Harold C. Lowrey. A descriptive article of a part of Canada which is little known to Canadians generally, Temagami.

"Petite Simunde." By Arthur Beverley Baxter. Illustrated by E. J. Dinsmore. A charming romance of the war. The author will be remembered favorably for his "Mr. Craighouse of New York, Satirist."

"The Seven Blue Doves." By W. A. Fraser. Illustrated by Charles L. Wrenn. The fifth of the Bulldog Carney series and in some respects the best. It is a mystery story.

"His Majesty's Well-Beloved." By Baroness Orczy. Illustrated by C. F. Peters. The second instalment of this splendid romantic novel of the colorful era of Charles II.

The Month's Vital Question

Turn to page 34, August MACLEAN'S, and you will find timely and interesting information regarding the High Cost of Living—a problem of large proportions.

The Review of Reviews

Here are a few of the articles chosen as the best published during the past month in all magazines:—Britain Winning Supremacy of the Air; Has Japan Two Governments?; Kaiser Employed Famous Beauties; The New Triple Alliance; Mammoth Animals in Alberta.

NOTICE

TO

Stationary and Hoisting Engineers

Everyone operating a STATIONARY steam plant of 50 h.p. or over in the Province of Ontario must hold a Stationary Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Everyone operating a HOISTING steam plant working at a pressure of 20 pounds or over, irrespective of horse power, and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a Hoisting Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Application forms for obtaining STATIONARY or HOISTING Engineers' Certificates, may be had upon applying to the Chairman.

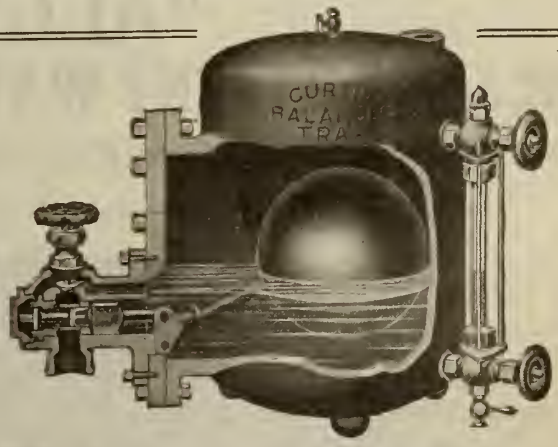
Power Plant thermometers for all temperatures not exceeding 1000° F

Also—"Columbia" Recording Gauges and Thermometers, Gauges, Gauge Testers, Tachometers, Steam Calorimeters, Counters, etc.

CURTIS Engineering Specialties



Five Superior Features of the Curtis Trap

1. A perfectly balanced valve.
2. An absolutely frictionless valve.
3. The valve can be removed without breaking a joint, starting a gasket, or taking out a bolt.
4. The valve being frictionless and balanced, the whole power of the float is available for opening and closing the valve.
5. Each trap will operate perfectly on pressure varying from one to 250 lbs.

Write for 1919 Catalog of Curtis Engineering Specialties.

JULIAN D'ESTE COMPANY

Main Office, 26 Canal St., Boston, Mass.

Agencies: 83 Barclay St., New York City
174 N. Market St., Chicago, Ill.

"I Bought

Diamond Soot Blowers, because efficiency of operation is the keynote of our production policies. Every piece of equipment in our boiler room was chosen on the basis of highest return on invested capital, character and scope of service considered.

"Among the specific reasons which led us to choose Diamonds are—design and constructional superiority —notable fuel and labor-saving ability—increase in overall efficiency, steaming capacity and flexibility of boiler plant."

Thus speaks the Power and Construction Engineer of one of the largest industrial plants in Canada.

If you operate a boiler plant of any size, from 100 H.P. up, and these reasons appeal to you, write for Bulletin 177.

DIAMOND SPECIALTY COMPANY
Windsor, Ont.

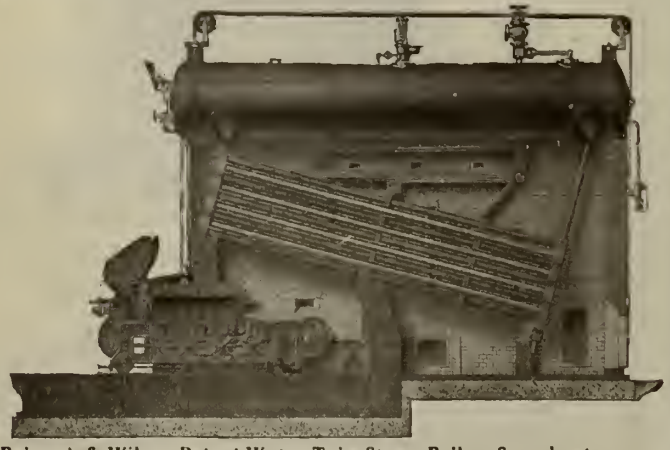
Diamond

SOOT BLOWERS - SAVE 4 to 8% FUEL

"ALL BRITISH"

"B.&W." PATENT WATER TUBE STEAM BOILERS

HIGHEST ECONOMY, SAFETY, DURABILITY. OVER 20,000,000 H.P. IN USE.



Babcock & Wilcox Patent Water Tube Steam Boiler, Superheater and Mechanical Stoker.

ALSO

Steam Superheaters
Mechanical Stokers
Coal-Handling Machinery
Piping, Feed Water Heaters
Water Softeners and Purifiers
and **ELECTRIC CRANES**

Babbitt
—Adjustable—
SPROCKET RIM
with Chain Guide

How Long Do You Require To Close Your Valves?

Those valves in that out-of-the-way corner, how quickly could you close them if necessity demanded? Would you have to hunt for a step ladder, or climb over obstructions? With a Babbitt Safety Sprocket Wheel and Guide it is as easy to close the most out-of-the-way valve as those closed by your hand. No climbing, no delay. Danger to property and workers is thus minimized.

Write for a catalog.

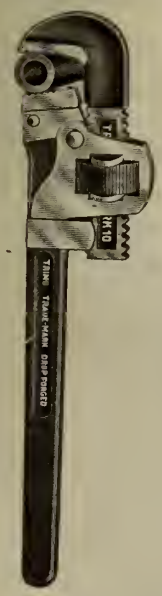
The Wrench of 25% Greater Efficiency

TRIMO PIPE WRENCH



Two new features have been recently added to the Trimo Pipe Wrench, namely Nut-Guards, in all sizes, and unbreakable steel frames, in leading sizes.

The Nut-Guards prevent the accidental rotation of the nut while in use.

These improvements add 25% to the usefulness of the tool.

The Trimo Pipe Wrench is made with wood handles in 4 sizes, 6-in., 8-in., 10-in., 14-in. and in steel handles in all sizes, 6-in. to 48-in. inclusive.

All Trimo Pipe Wrench parts are interchangeable.

The inserted jaw in the handle can be readily replaced when worn, thus adding to the life of the tool.

Nut with Nut-Guards

That's why you get continuous service from

LUNKENHEIMER "RENEWO" VALVES

The "seat guard" with which the "Renewo" is provided aids in preserving the seating surfaces and keeping them clean. The seating surfaces are regrindable and all the parts, including the **seat ring** and **disc** are renewable. To further enhance their durability, both the **seat ring** and **disc** are made of Lunkenheimer "Valvenickel" — a material having exceptional wear resisting qualities.

The body, bonnet, stem, etc., are made of high-grade bronze composition formulated especially for the duty each part performs, making the **"Renewo"** the most practical, durable and economical valve to be had.

Globe, Angle, Cross, Straightway and Horizontal and Angle Check types for pressures up to 200 and 300 pounds.

Specify **Lunkenheimer "Renewo"** and insist on getting the genuine. Your local dealer can furnish them, if not, write us.

Write for Booklet No. 535—DC.

Yale Chain Blocks

"from hook to hook a line of Steel"—provide the strongest, quickest and easiest means of hoisting, no matter what kind of plant you operate.

The parts are few and simple, they have the greatest overload capacity, the chain is tested to two and a half times its capacity, the gears centre around one main shaft.

In short, the Yale is the most practical of all hoists.

No matter what kind of loads you have to handle—no matter what difficulties there are to be overcome, the Yale meets the contingency. Before you equip your plant, or replace old equipment, investigate the Yale.

Scale in Your Boilers

Clean Tubes Mean Coal Saving

And easier firing, less ash-handling, fewer shut-downs, prevention of bagged or burned tubes, fewer repairs, and less frequent wash-outs. METLSKIN can pay for itself in a short time.

is an unprofitable boarder. Its appetite is enormous and it consumes far more than it is worth. Why not give it TWO MONTHS' NOTICE, and put an end to your loss thereafter?

THE SIXTY-DAY TEST OF METLSKIN is open to any reliable concern that is troubled with boiler-scale, pitting or corrosion. A small daily dose of METLSKIN, for a period of two months, will bring down the most tenacious scale, and absolutely convince you that A CLEAN BOILER IS NOT ONLY POSSIBLE, but EASY.

SEND A POSTCARD for the METLSKIN booklet and learn about Our Offer, Guarantee Bond, and Prices.

METLSKIN is neither "Compound" nor "Cure-all."

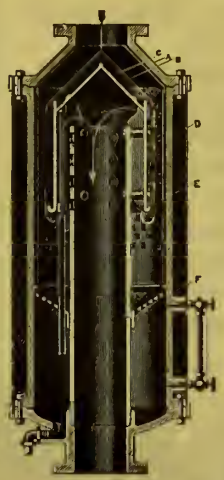
III IMPORTANT THINGS

TO CONSIDER ABOUT
A SEPARATOR



I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE—Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION—Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

FAIRBANKS-MORSE
EVERYTHING MECHANICAL

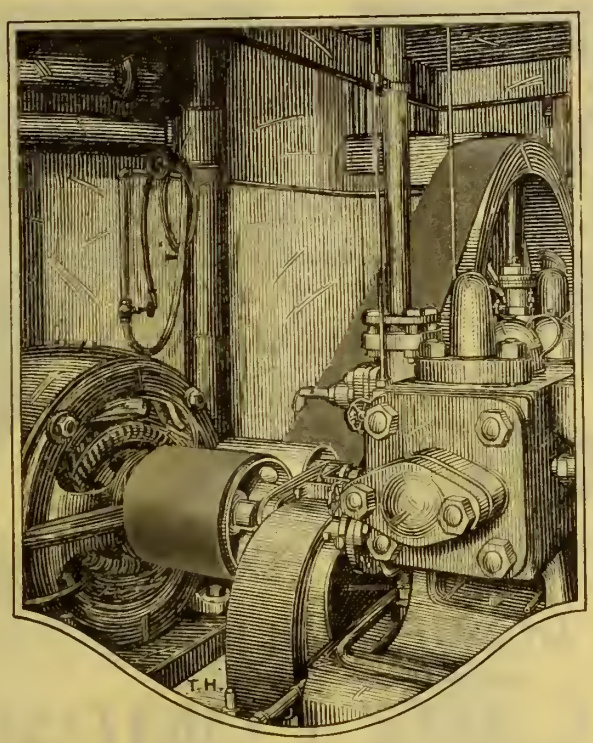
Do you know that the centrifugal force in belts at high speed reduces their driving power until at about 9600 R. P. M. a belt is incapable of transmitting power? All such factors are taken into account by our Engineering Department when they design standardized belt drives. Consult them about your problem.



This is a 12-inch Spartan Double Belt, operating a 50 horse-power Gas Compressor. Its cost to date is ½c per horse-power per week. When this belt had been in use 18 months, the engineer wrote us that it had given double the length of service of belts previously used. This has now been in use over four years and is still going strong.

TOP NOTCH

There is another case where top-notch efficiency and economy have been obtained by simply installing the right belt for the work to be done.

For many years Spartan Belting has been dominating the hard drives that destroy other belts. That experience ranks it as top notch in leather, in tannage and in workmanship. It is unusually pliable, wonderfully elastic, it is the greatest of pulley grippers and without an equal for high speed, overload drives or where unfavorable conditions exist.

Spartan well exemplifies the three principles back of Graton & Knight Standardized Series Leather Belt: First, they are made of the right material—leather. Second, they are tanned in our own tannery specifically for belting use, thus assuring the right kind of leather. Third, they are graded into a Standardized Series—a belt for each class of power transmission requirements—standardized in manufacture and standardized for the work to be done.

Certain articles can be tested in a short time—not so belting. It takes years to test out the correctness of principles applied in power transmission. The result of 60 years test of experience is that Graton & Knight Standardized Series Belting, the highest in grade, is also the most widely sold. That is a significant combination: highest quality—largest sale.

Many of the best belted plants ask us to specify the belting for every drive. Try the plan yourself. Then, when buying, call for "Graton & Knight—— Brand or equal." This won't commit you to buying our belts. It will put your buying on the one basic consideration—the work to be done.

DURABLA

STRENGTH—GOODNESS—QUALITY
WATER

Many miles of boiler feed lines carrying water at a temperature of approximately 210 deg. F. have never leaked because the flanges were packed with DURABLA gasket material. Equally satisfactory service is being given by DURABLA on lines where the temperature of the water is 40 deg. F. DURABLA does not pulp and this fact has convinced others that it is a standard for all water service.

Put DURABLA in the next water joints you make and it will prove this fact to you. It is guaranteed to make a tight joint.

DURABLA gasket material is also guaranteed for oil, air, steam, ammonia, gasoline and acids.

One Standard Material for All Gasket Work. Sold on a Service Basis.

The Cost of Packing a Small Valve

Do you know what constitutes the cost of packing a globe valve?

It's not the small amount of packing required, but the labor of applying it. To reduce the cost of packing the many small valves about your plant select a packing that is made of first grade materials and has the reputation of giving long, satisfactory service, and so reduce the labor cost, which is really the controlling item of expense.

If your engineer has something more important to do than packing small valves provide him with "Palmetto" twist packing.

IT MEANS REAL ECONOMY

Any size valve packed from one spool by unstranding.

The Floating Head Allows for Unequal Expansion of Hot and Cold Tubes

There can't be trouble from expansion or contraction strains, because of this Alberger Multi-Head free from the cast iron shell of this

Alberger Heater

Nor can there be clogging of the tubes, for these Alberger tubes are corrugated pure copper. These corrugated tubes will remain scale-free longer than a heater with plain tubes, because the corrugations promote a scouring effect on the tubes.

Brass tubes are a source of expense, because they frequently split. But Alberger tubes are pure copper; they will neither split, bend nor buckle.

Keeps up with the heaviest hot water demands.

Because Alberger Heaters transmit 50% more heat than plain tube heaters of corresponding size. Alberger Heaters furnish hot water as fast as it can be drawn. You will use less fuel and need no storage tank with an Alberger Heater.

Voorhees Rub-Steel Valves

"The Valve with a backbone"

Are without an Equal for

Deane of Holyoke Condensers

or Suctions on Paper Machines

Softest high-grade rubber as seating, supported by an inseparable **steel core.** Spring guides and brass bushed stud-holes as above, if desired, or plain faces.

Not a cheap valve, but positively smoothest in action and longest lasting.

This construction in Four Grades for **every** known pumping service.

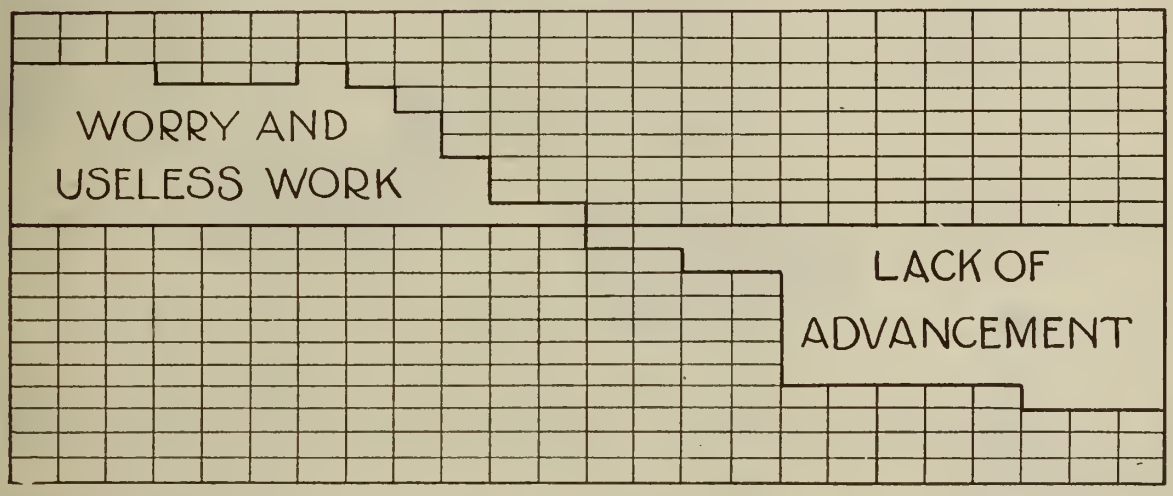
Let the C.A.S.E. Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

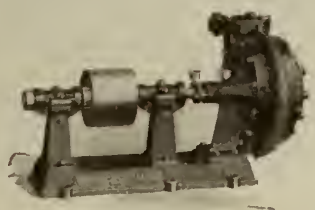
AMERICAN-MARSH PUMPS

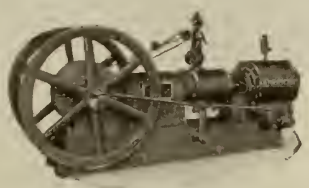
SIMPLE RELIABLE EFFICIENT

The American-Marsh steam pump is an improved form of the famous Marsh Pump which has been on the market for over thirty years, during which time over 150,000 have been manufactured and sold.

The American-Marsh Pump has no internal stuffing boxes, no tappets and no slide valves. The auxiliary valve is of the semi-rotative disc type of an improved design. The main steam valve is of the balanced piston pattern, assuring highest efficiency. The water ends have large valve areas and are fully bronze fitted, including solid bronze piston rods and bronze removable water cylinder bushings.



American-Marsh Centrifugal Pumps are made with the same high grade of material and workmanship which characterizes the construction of the steam pumps. They are made in all sizes up to 12 inch, both single and two stage for heads up to 250 feet.



The line also includes—

Power Pumps
Deep Well Engines
Air Compressors
Jet Condensers
Dry Vacuum Pumps
Boiler Feed Pumps

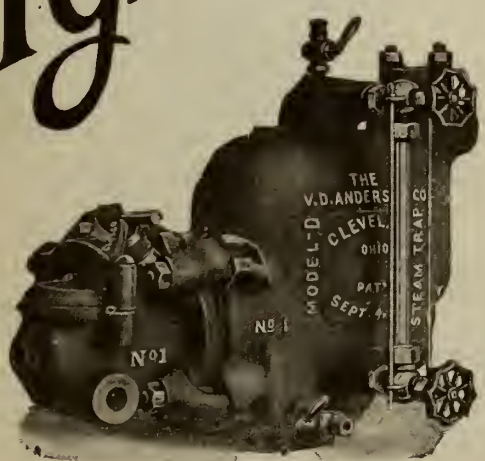
Stays Tight



The ANDERSON Model "D" Steam Trap

Just think of the satisfaction you have once this perfected trap is in your steam-room!

Tight from the day you put it in! Of that you can be sure.

It is operated by a counterbalanced Lake Superior Copper Float. Its large air valve is ever under deep water seal, and never will it wire draw.

Furthermore, every part is machined to solid gauge. Self-contained strainer and self-contained by-pass are Anderson features. Note the outside gauge glass. And the simple design! It gives you complete accessibility to every part.

Write for full particulars.

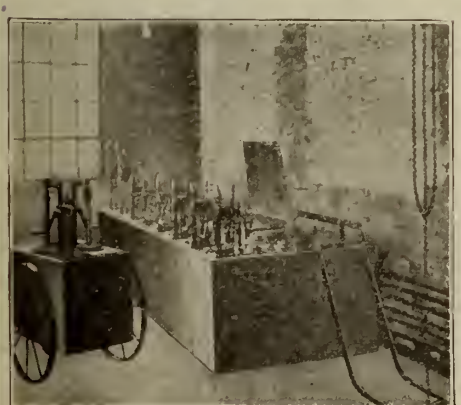
Stop Wasting That Oil !

You don't allow castings, finished parts or supplies to lie around without an accurate record of them. Such things go into the store room, carefully checked in and charged out as used—Why?—It is the only safe, systematic way to do.

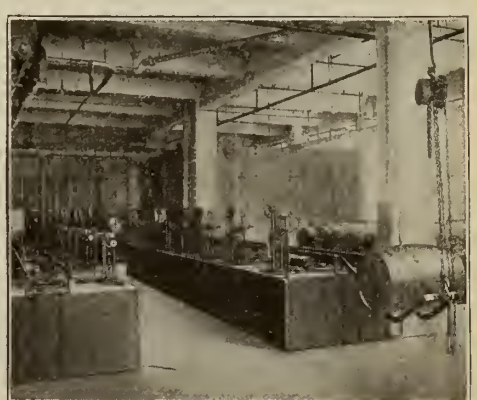
Are your oils handled as carefully? They can be, and can be accounted for as easily as other materials—receipts checked, accurate quantities given out, charges made to the departments using and records kept if desired.

BOWSER Storage Systems



BOWSER Lubricating and Paint Oil Battery Installation with Portable Outfit for Lubricating Oil

Save the Oil



Double Battery Installation for Paints and Other Oils, one unit or as many as needed can be installed.

Bowser Systems enable workmen to get full value from every drop of oil, save a great amount of time and labor in handling.

Put your Oil storage problems up to the Bowser engineers. Let them make a survey of your plant, show you just what you may expect to save by the use of Bowser oil handling equipment. It costs you nothing and it should mean a saving for you. *Write us today for further information.*

WE STRIVE TO EXCEL

DEFENDER

DUPLEX DRAFT GAUGE

The Peer of Them All

Price $20.00

They read: Draft over the fire. Draft at the last pass of the Boiler and the differential through the Boiler.

THE FIREMEN CONTROL the fires by the readings on the Gauge. It shows every condition of the Fires and Boilers, except Flue Gas Temperatures and the Defender Flue Gas Pyrometers show the Flue Gas Temperatures. Also see the Defender CO_2 Analysers, put up in permanent case so as to take a reading for CO_2 in less than one minute's time. Write for Bulletin No. 100.

Defender Catalogue No. 11 shows the largest assortment of Combustion appliances, efficiency instruments and damper regulators made. We can help you save fuel.

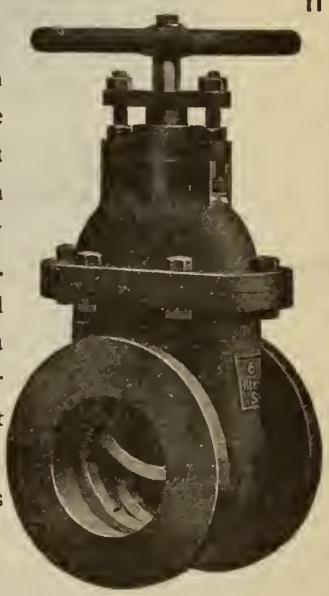
DEFENDER AUTOMATIC REGULATOR CO., 709 Pine St., ST. LOUIS, MO.

KERR

("New KEYSTONE" Pattern) GATE VALVES

If you have not used any of these New Pattern Valves, specify "KERR" in your next order. We want you to get acquainted with the most reliable valve on the market.

If you have been using them, we are confident that our satisfaction will bring us your repeat orders. These valves will never cause you or your customer the slightest trouble. Their high quality is consistent.



When you buy a "KERR" Valve you get a guaranteed article that is backed by a reliable firm. Many of the largest distributers of valves in Canada have sold "KERR" Valves for over 25 years, and are still recommending them as the "Best Valve." Write us for particulars.

Write For Bulletin 51

it's just off the press

A medium pressure valve combining the best in design, materials and workmanship.

"ATLAS" valves are designed for a working steam pressure of 150 lbs. per square inch and are subjected to a hydraulic test of 300 lbs. per square inch before leaving our factory.

We are prepared to furnish promptly any of the sizes listed in our bulletin, and guarantee the valves to fulfill in every respect all that we claim for them.

All of the wearing parts can be renewed should they become worn or broken.

TRADE PENBERTHY MARK

REGRINDING BRASS VALVES

With the Metal Disc

Registered and Approved For
200 Lbs. Steam Pressure in Ont. and Western Provinces

Used Exclusively in Many of
the Leading Manufacturing Plants in Canada

We Were the First

To manufacture in Canada this high grade line of brass valves, and the demand is ever-increasing owing to the reliable and dependable service they give under high pressures and severe conditions.

It is the result of many years of practical experience in the manufacture of exclusive high grade brass goods and the valves embody the latest and most progressive mechanical ideas employed in valve construction.

The Outside Bonnet Construction

is used on all Penberthy Regrinding Valves. This feature permits easy accessibility to valve at any time because the threads on the bonnet end of body being on the outside makes the connection absolutely non-corrosive and the valve can be taken apart without strain or injury to any part.

When You Want the Best Valve, Specify "Penberthy"

Manufactured by

PENBERTHY INJECTOR COMPANY, LIMITED, WINDSOR, ONTARIO

IMPERIAL

Lubricants

The Secret of Mechanical Efficiency

TIME will be served. Present day competition and speeding-up of power plants and machinery will tell its inevitable tale unless the proper lubricants are used for each and every requirement.

The necessity for thorough, systematic lubrication is recognized by all successful manufacturers. Correct lubricants lengthen the life of machinery, increase its production capacity, reduce fuel consumption and repair bills. Poor lubricants are expensive at any price.

Correct lubrication makes your mechanical department just as much a dividend producer as any other department. It is not what you pay per gallon that counts, but how much real lubrication you get per dollar.

Choose your lubricants from the Imperial line. Scientifically formulated, carefully graded, designed for specific purposes, their continued use will add much to the efficiency of your machinery, enabling it to withstand all demands.

"Belting trouble ends where D.K. McLaren's Belting begins"

The fact that a large percentage of our business comes in the form of repeat orders proves that D. K. McLaren's belting gives most satisfactory service.

Put

D. K. McLaren's

Genuine British Oak Tanned

Leather Belting

on the hardest belt-wearing drive in your plant and then forget to worry about it.

D. K. McLaren's belting has stood the quality test in many of Canada's largest power houses after other beltings had fallen down. It will do the same in your service.

The reason is—only flawless backs are used and our Genuine British Oak Tanning process preserves all the hide's natural strength. Minimum stretch, minimum slippage, and few breaks are characteristics of belting made in this way.

After the belt has more than paid for itself on the main drives, it can be cut into smaller belts and kept earning.

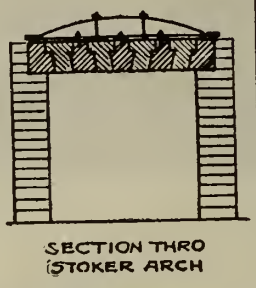
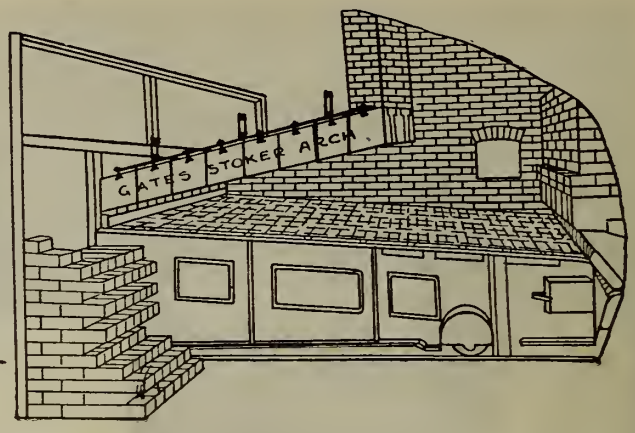
GATES STOKER ARCH

Means Cutting your Cost of Upkeep and Fuel Bills





Our stoker arches are designed to promote combustion and give longer life.

Our door arches and jambs are made to withstand the strong-armed boy with the slice bar.

Our side wall blocks are made to eliminate the many joints that clinkers stick to, when ordinary fire brick is used. They give longer life and reduce air leaks to a minimum.

WE DESIGNED THESE ARCHES AND BLOCKS SO THAT ANY HANDY MAN COULD REPLACE SAME IN HALF THE TIME THAT IT TAKES TO REPAIR A STANDARD FIRE BRICK JOB.

Manufacturers of all types of Baffles and Special Shapes.

Call on our Engineers at any time for further information. Their services are offered without obligation.

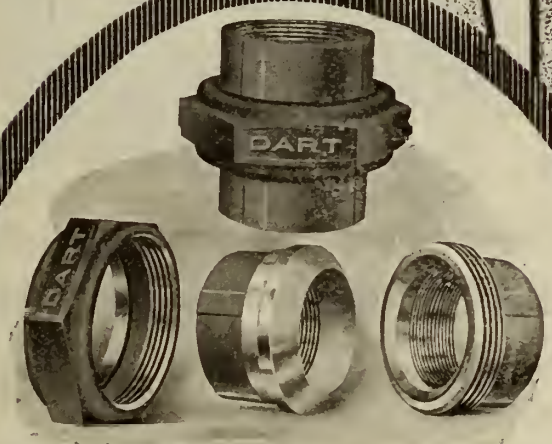
Entered as second-class matter at the Post Office Department, Ottawa, Canada. Entered as second-class matter July 1, 1912, at the Post Office at Buffalo, under the Act of March 3rd, 1879.

DART



The Union Pipe Coupling of SECURITY

BRONZE To Bronze at the joint

WHEN you connect pipe lines with the Dart Union you have made a joint that will never loosen up and leak.

The "Dart" efficiency is practically everlasting, because—BRONZE (a non-deteriorating metal)—forms the Face and Seat, and the Heavy Malleable Iron Pipe Ends and Nut insure strength and durability.

Another important feature of Dart Unions is the Ball-Shaped Joint—this allows for an easily made and tight connection whether pipes are in or out of alignment.

Ask your jobber for a working sample.

Manufactured by

Dart Union Co., Limited, Toronto

TALBOT

Contra-Flow Steam Boilers

(Equipped with Crude Oil Burners)

Reduces Steam Cost

The cost of operation is cheaper than any known power product.

Require one-seventh the space of the ordinary boiler.

No brickwork is necessary.

Feed water and fuel burners are automatically controlled to adjust the boiler to varying demands for steam.

Tubes easily replaced under high steam pressure.

1-1000 H.P. Boiler in stock, immediate delivery.

May we send you the full details?

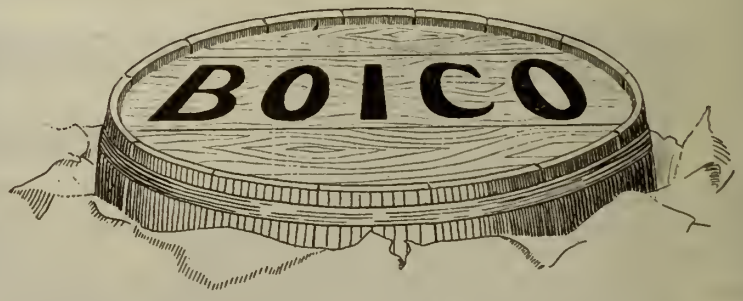
The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.** BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.



Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

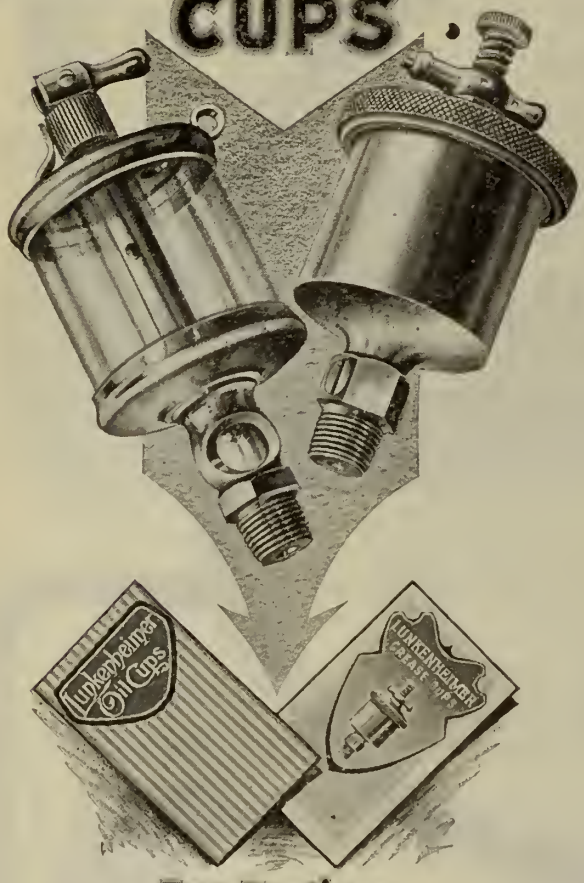
LUNKENHEIMER
OIL AND GREASE CUPS



For Engine AND Transmission Bearings

By their unfailing reliability have won the reputation they enjoy. The engineer specifying "Lunkenheimer," knows that bearings thus equipped will get the amount of lubricant for which the feed is set—uniformly, until cups are empty, and that no further attention is necessary other than filling.

They are practical and durable; the feed regulation is simple and easily adjusted, and there is no danger of unsetting the feed when refilling.

The variety of types made embraces **Oil Cups** with Glass or Bronze Body, with or without Sightfeed; and **Grease Cups** of Bronze, Iron and Steel, with Screw or Spring Compression feed—a type for every service requirement.

Write **"Lunkenheimer—equipped"** in your engine and transmission specifications, and insist on having the genuine.

Descriptive Booklets Nos. 523 and 524-DC — will assist you in selecting the proper styles. Write for copies.

This is a 12-inch Spartan Double Belt, operating a 50 horsepower Gas Compressor. Its cost to date is ½c per horsepower per week. When this belt had been in use 18 months, the engineer wrote us that it had given double the length of service of belts previously used. This has now been in use over four years and is still going strong.

TOP NOTCH

This is another case where top-notch efficiency and economy have been obtained by simply installing the right belt for the work to be done. Spartan, the belt illustrated, well exemplifies the three principles back of Graton & Knight Standardized Series Leather Belts: First, they are made of the right material—leather. Second, they are tanned in our own tannery specifically for belting use, thus assuring the right kind of leather. Third, they are graded into a Standardized Series—a belt for each class of power transmission requirements—standardized in manufacture and standardized for the work to be done.

What They Say About Power House

"I certainly am in favor of a semi-monthly publication. In my opinion it cannot be published too often. I have been several times around the world as an engineer in the British Merchant Service and POWER HOUSE is the best paper of its class I have ever met."—Mr. Percy S. Hunter, Donavon, Sask.

"I would like very much to get POWER HOUSE twice a month. For Canadian engineers it is unexcelled."—Mr. A. R. Troke, Paris, Ont.

"New subscribers who do not really know the value of POWER HOUSE might demur at paying a high price for it, but personally speaking, I would not object to paying double price for double service. I never miss reading the advertisements. They are real interesting to anyone in this line."—Mr. Fred E. Reesar, Municipal Electric Light Plant, Markham, Ont.

"I feel that a semi-monthly magazine will also be a great step in our favor inasmuch as we can now look forward to a friend and adviser's call twice a month instead of once. I take a number of magazines myself, but there is none I look forward to receiving like my old friend and adviser, POWER HOUSE."—Mr. L. E. Wight, Drumheller, Alberta.

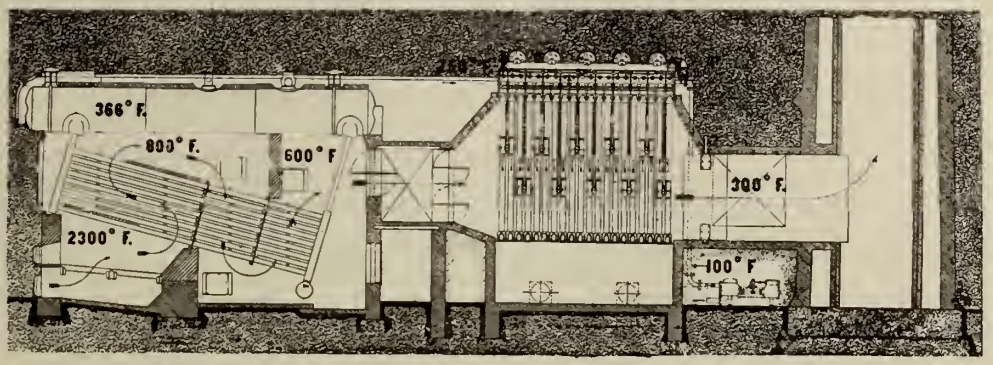
"I favor the change to semi-monthly. It is worth twice the money to a Canadian engineer when compared to other magazines published in the U.S.A., upon which I am basing this suggestion."—Mr. Fred R. McNeil, Shawinigan Falls, Q.

"I am very pleased to hear that POWER HOUSE is to be published twice a month as I have been a reader of it for several years. The change will be a great help to engineers."—Mr. W. E. Dale, Vancouver, B.C.

and Hundreds More Say the Same

GREEN'S ECONOMISERS

showing feed water rise of 150°F. Or a saving of 13.6%, based on 1% saving for each 11° increase in feed water temperature.



It does not pay to use extra boiler surface to cool the gases below 500° F.

Because below 500° F. the value of heat absorbed per square foot of heating surface does not equal the cost of maintenance.

It pays well to use Green's Fuel Economisers to cool the gases to as low as 250° F.

Because the heat absorbed by the boiler feed water at 100° F. is much greater than that absorbed by the steam and water at about 366° F. in the boiler. Also the economiser surface costs less to install and maintain.

POWER HOUSE

Established 1907 — Published Semi-monthly

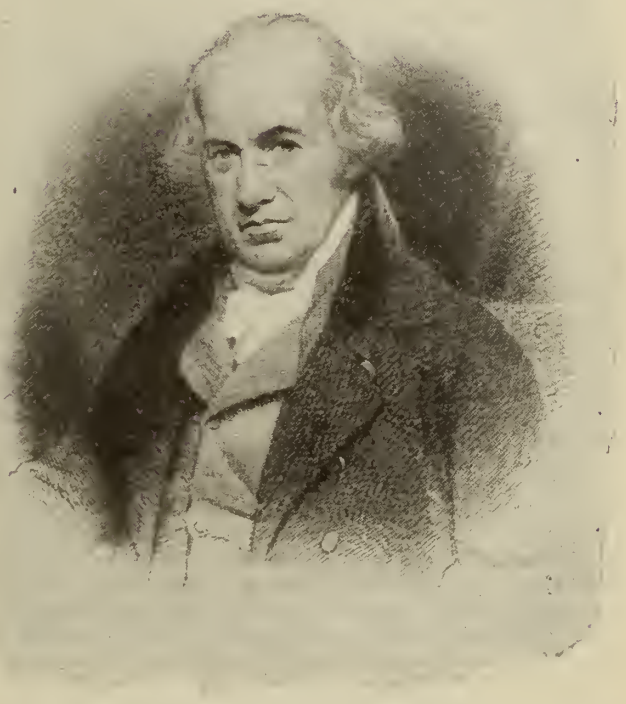
JAMES WATT

The Father of Modern Industry and Commercial Progress

By W. F. Sutherland

"Not to perpetuate a Name
Which must endure while peaceful arts flourish,
But to show
That mankind have learned to honour those
Who best deserve their gratitude,
The King,
His ministers, and many of the nobles
And commoners of the realm,
Raised this monument to
JAMES WATT,

Who directing the force of an original genius,
Early exercised in philosophic research,
To the improvement of
The Steam-Engine,
Enlarged the resources of his country,
Increased the power of man,
And rose to an eminent place
Among the most illustrious followers of science
And the real benefactors of the world."



SUCH was the epitaph penned by Lord Brougham. Wordsworth has said that he looked upon him, considering the magnitude and universatility of his genius "as perhaps the most extraordinary man that this country (England) has ever produced." And while these eulogiums were written long before the present era of industrial activity his genius is all the more apparent in the changes it has wrought.

James Patrick Muirhead, in his "Life of James Watt," published in 1859, gives us some interesting facts relating to the family life of Watt and to his life in general. The family of Watt is first found in Aberdeenshire, and his great-grandfather, it is said, perished in one of the wars of Montrose, his property being confiscated and his orphan son later settling near Greenock. This son, Thomas Watt, was a teacher of navigation or, as he is styled, on his tombstone, a teacher of mathematics; so that James Watt's genius may find some explanation in the natural bent of his grandfather. At this date, Greenock was little more than a fishing hamlet, and Thomas Watt was so important in the affairs of the small community that he was made its chief magistrate, an elder of the parish as well as treasurer and clerk to the Kirk session. In these capacities he repaired the church, widened the bridge, and adjusted the weights and measures of the burgh by his standards. He imposed fines for the pranks of the roysterers on Hallowe'en night, regulated the keeping of "taim foules" and their scratching in gardens, discouraged the "sitting in and haunting of taverns on Friday and Saturday night," and also the "guilt of skippers" in "loosing their ships and taking them to seaward on the Sabbath day." The great feat of his administrative reign was his supposed discrimination in dealing with the complicated pretensions of a certain mountebank medicine vendor. To this worthy he forbade the attraction of "saltatory lassies and their demonstrative rope dancing" while he allowed him to expose his wares for sale.

Thomas Watt died in 1734, at about the age of ninety-five, leaving two sons, John and James, the latter being the father of James Watt. James Watt, the father, was a ship-chandler (supplying vessels with nautical apparatus, stores, and instruments), a builder and a merchant. He married Agnes Muirhead, herself a woman of exceptional attainments and striking qualities of her own. She had other children of whom three died in infancy or early childhood and one of whom was drowned at sea.

James Watt, the son, was born on the 19th day of January, 1736. His constitution was delicate and his mental powers precocious. There is a story of his having been observed, as a child of six years old, drawing mathematical lines and circles on the hearthstone. The famous story of his studying the condensation of steam while he was playing with the maternal tea-kettle, and while yet a boy will also be brought to mind and whether it be authentic or not it has been made the subject of a pretty picture and will ever remain a basis for speculation and inspiration.

During his early years Watt was sent to a commercial school where he was provided with a fair knowledge of Latin and some small smattering of Greek. But mathematics were his favorite study and "while under his

father's roof he went on with various chemical experiments, repeating them again and again, until satisfied with their accuracy. He even made himself a small electrical machine about 1750-53—no mean performance at that date.

From the aptitude which he displayed for all kinds of ingenious handiwork, and in accordance with his own deliberate choice it was decided that he should qualify himself for the trade of mathematical instrument maker and accordingly he proceeded to Glasgow in June, 1854, and a year later to London, where his education in things mechanical really commenced under the tuition of John Morgan, an instrument maker in Finch Lane. Cornhill. Here he gradually became profficient in making quadrants, parellel rulers, compasses, theodolites, etc., and on leaving London in 1756 was possessed of a considerable fund of knowledge.

Settling in Glasgow he was first employed in cleaning and repairing some of the instruments belonging to the College Museum and, restricted by municipal regulations from the uncharted pursuit of his trade or craft, was supported by the University. By midsummer, 1757, he had received permission to occupy an apartment and to open a shop within the precincts of the college, and to use the designation of "mathematical instrument maker to the University."

Among other developments of his skill, he undertook to construct an organ, studying for the purpose the whole theory of harmonies. "Fiddles also did he make, and if entreated mend."

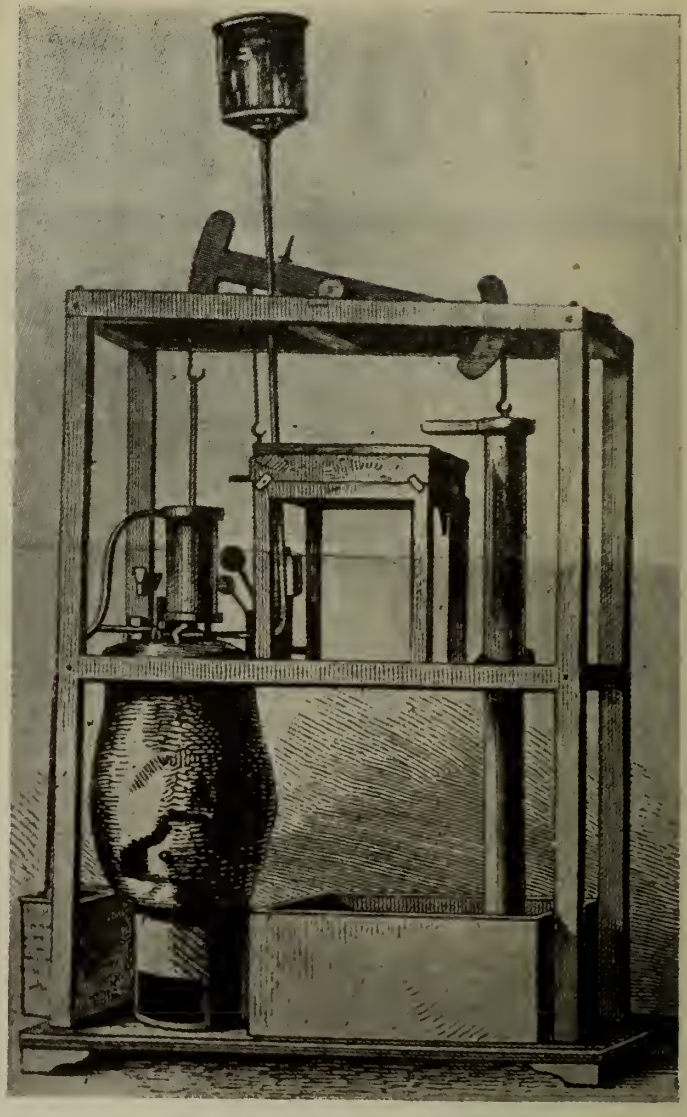
In 1763 he quitted his college rooms for a small abode in the city in contemplation of his marriage with his cousin, Miss Miller, to whom he had been long attached and with whom he was united in the July of the following year.

Watt's devotion to philosophical pursuits procured for him about this time the notice and friendship of Dr. Black, Professor of Anatomy, and afterwards of Medicine, in Glasgow College. In 1758 he also made the acquaintance of another university worthy, John Robinson; and both these learned persons have left interesting narratives concerning him. The latter tells of his introduction to Watt. "I saw a workman," says he, "and expected no more, but was surprised to find a philosopher as young as myself and always ready to instruct me." Watt's parlor had at this date become a rendezvous for all the loitering persons scientifically inclined. "Whenever," says Robinson, "any puzzle came in the way of any of us we went to Mr. Watt. He needed only to be prompted; everything became to him only a new and interesting study; and we knew he would not quit it until he had discovered its insignificance or had made something out of it. No matter in what line—language, antiquity, natural history, nay poetry criticism and works of taste; as to anything in the line of engineering, whether civil or military, he was at home and a ready instructor."

Watt's greatest contribution to the welfare of man came about while repairing a model of Newcomen's steam engine at the request of the Professor of Natural Philosophy in the University. This model was at first a plaything to Watt and Robinson, then a constant visitor at his workshop; but like everything which came into his hands, it soon became an object of most serious study.

The engine with which Watt became interested wasted about three-fourths of the steam through condensation on the up-stroke, owing to the cooling effect of the walls and piston from the injection of water on the previous down stroke for condensation. Robinson, in his record of this discovery, says:

"At the breaking up of the College (in 1765) I went to the country. About a fortnight after this I came to town and went to have a chat with Mr. Watt and to communicate to him some observations I had made on Desagulier's and Belidor's account of the steam engine. I came into Watt's parlor without ceremony and found him sitting before the fire, having lying on his knee a little tin cistern which he was looking at. I entered into conversation on what we were last speaking of—



NEWCOMEN ENGINE MODEL REPAIRED BY WATT.
—The "National Engineer."

something about steam. All the while Mr. Watt kept looking at the fire and laid down the cistern at the foot of his chair. At last he looked at me, and said briskly, 'You need not fash yourself any more about that, man; I have now made an engine that shall not waste a particle of steam. It shall be boiling hot—aye, and hot water injected, if you please.' So saying, Mr. Watt looked with complacency at the little thing at his feet, and seeing that I observed him, he shoved it away under a table with his foot. I put a question to him about the nature of his contrivance. He answered me rather drily. I did not press him further for an explanation at that time, knowing that I had offended him a few days before by blabbing a pretty contrivance which he had hit on for turning the cocks of an engine. I had mentioned this in the presence of an engine-builder who was going to erect one for a friend of mine, and this having come to Mr. Watt's ears, he had found fault with it."

"I was very anxious, however, to learn what Mr. Watt had contrived but was obliged to go to the country in the evening. A gentleman who was going to the same house said he would give me a place in his carriage, and desired me to wait for him on the walk by the riverside. I went thither and found Mr. Alexander Brown, a very intimate acquaintance of Mr. Watt's, walking with another gentleman (Mr. Craig, architect). Mr. Brown immediately accosted me with, 'Well, have you seen Jamie Watt?' "Yes." 'He'll be in high spirits

with his engine, isn't he?' "Yes," said I, "very fine spirits." 'Gad!' says Mr. Brown, 'the condenser's the thing; keep it but cold enough, and you may have a perfect vacuum whatever be the heat of the cylinder.' The instant he said this the whole thing flashed on my mind at once. I did all I could to encourage the conversation, but was much embarrassed. I durst not appear ignorant of the apparatus lest Mr. Brown should find that he had communicated more than he ought to have done."

In the summer of 1767 the whole contrivance was perfect in Watt's mind and so well defined there was the date of his invention, that on being asked in 1817 whether he recollected how the first idea came to him he replied, "Oh, yes, perfectly. One Sunday afternoon I had gone to take a walk in the Green of Glasgow, and when about half way between the Herd's house and Arn's well, my thoughts having been naturally turned to the experiments I had been engaged in for saving heat in the cylinder, at that part of the road it occurred to me that as steam was an elastic vapor, it would expand and rush into a previously exhausted space; and that if I were to produce a vacuum in a separate vessel, and open a communication between the steam in the cylinder and the exhausted vessel such would be the consequence."

To further his object of keeping the cylinder as hot as the steam that entered it, Watt supplemented his great invention of the separate condenser by several less notable but still important improvements. In Newcomen's engine a layer of water over the piston had been used to keep it steam tight; Watt substituted a tighter packing lubricated with oil. In Newcomen's engine the upper end of the cylinder was open to the air; Watt covered it in, leading the piston rod through a steam-tight stuffing box in the cover, and allowed steam instead of air to press on the top of the piston. In Newcomen's engine the cylinder had no clothing to reduce the loss of heat by radiation and conduction from its outer surface; Watt not only cased it in non-conducting coverings such as wood, but introduced the steam jacket.

All of these features were specified in his first patent which, however, was not obtained till January, 1769, nearly four years after the inventions it covered had been made. In the interval Watt had been striving to demonstrate the merits of his engine by trial on a large scale. His earliest experiments left him in debt and, finding that his own means were quite insufficient to allow him to continue them, he agreed that Dr. John Roebuck, founder of the Carron ironworks, should take two-thirds of the profits of the invention in consideration for his bearing the cost. An engine was then erected at Kinneil where Roebuck lived, giving Watt an opportunity of facing many difficulties in construction. But the experiments made slow progress, for Roebuck's affairs became embarrassed and Watt's attention was drawn to other more remunerative work by his own pressing needs and those of his family. He had taken to surveying and gained considerable reputation as a civil engineer. In 1767 he was employed to make a survey for a Forth and Clyde canal—a scheme which failed to secure Parliamentary sanction. This was followed by other surveys for canals and plans for harbors, etc. In the course of his work he invented the micrometer for measuring distances, consisting of a pair of horizontal hairs placed in the focus of a telescope through which sights were taken to fixed and movable targets on a rod at the place whose distance from the rod was to be determined.

Meanwhile progress had been made on the steam engine, the Kinneil trials had yielded him a store of valuable experience. Roebuck had failed, but another partner had been found in Matthew Boulton, a man of energy and capital, who owned the Soho engineering works at Birmingham.

Watt's arrangements were facilitated by the concurrence of Dr. Roebuck's creditors, because curiously enough, none of them valued his engine at a farthing; and for him, as for so many other men, success seemed to dawn at the moment when he was ready to despair of its possibility. For many years previously he had complained of his headaches and of almost constant ill-health; of what he called laziness, stupefaction, and confusion of ideas, which partially meant the mental weariness of unrecompensed toil.

Yet while in 1774 at his abode in Birmingham he was able to write to his father that "the fire-engine that I have invented is now going and answers much better than any other that has yet been made; and I expect that the invention will be very beneficial to me." A long series of trials was nevertheless necessary before the engine could be brought to the stage where it would be generally available to the public and profitable to the manufacturers.

In January, 1775, six years of the patent had elapsed and there seemed some probability of the remaining eight running out as fruitlessly. An application which was made for the extension of its term was unexpectedly opposed by the eloquence of Burke, but the orator and his associates failed, and the extension was accorded by act of Parliament. Such, however, was the low state of engineering arts that much difficulty was encountered in getting the parts of the engines fabricated with the necessary accuracy. At this turning point in his life Watt married again and narrowly escaped expatriation through an offer of employment from the Russian Government.

The first practical employment of Watt's engines to any considerable extent was in the mining districts of Cornwall, where he was himself in consequence, forced to spend much of his time. He had to contend not only with the natural obstacles in the dark abysses of deeply-flooded mines, but with a rude and obstinate class of men as deeply flooded by inveterate prejudices. After he had "forked" the heaviest waters in the whole county to his previous efforts was added the more odious task of having to observe and restrain the piracies which began to occur, at first secretly, but afterwards with greater frequency and daring. Speaking of Cornwall, he says: "Those wilds might be defined as a tract of hills without dales where the roads went straight up the hills without flinching and where (plumbing misery to its depths) the engine men actually eat the grease from the engine."

For some time royalties came in but sparingly to Watt and Boulton, but during this expectant stage Watt himself was more fertile in mechanical inventions than in any other portion of his busy life. Taking his patents in order the first subsequent to that of 1769 was for a new method of copying letters and other writings expeditiously, by means of copying presses. Of the same same date as his copying machine, was his invention of another machine "for drying linen and muslin by steam." On the 25th of October, 1781, he took out his third patent (the second of the steam engine series) "for certain new methods of applying the vibrating or reciprocating motion of steam or fire engines to produce a continued or rotative motion around an axis or centre and thereby give motion to the wheels of mills or other machines." One of these methods was that commonly known as the "sun and planet wheels." Later on he took out another, fourth, patent on the double-acting engine in consequence of his finding himself beset by a host of plagiaries and pirates.

Another patent in the steam engine series, taken out in 1784, contained besides methods of converting a circular or angular motion into a perpendicular or rectilinear motion the well-known and much-admired parallel motion of which Watt says, in a letter to Boulton, "I have started a new hare. I have got a glimpse of a method of causing a piston rod to move up and down perpendicularly by only fixing it to a piece of iron upon the beam, without chains or perpendicular guides or untowardly frictions, arch heads or other pieces of clumsiness. I think it a probable thing to succeed and one of the most ingenious pieces of mechanism I have contrived."

A still later invention was the throttle valve and centrifugal governor by which the speed of rotative engines was automatically controlled. One more item in the list of Watt's contributions to the development of the steam engine is too important to pass without men-

tion; the indicator was used by Boulton and Watt to measure the work done by their engines and so to give a basis on which the charges levied on their customers were adjusted.

Up to Watt's time, steam had been admitted for the whole length of the stroke and he was the first to conceive of the possibility of working it expansively, cutting off before the end of the stroke and so effecting a further economy in steam.

While Watt was thus busy with his steam engine and with other matters of a strictly engineering nature yet he found time for more philosophical pursuits and ventured into the realm of chemistry and physics. One of the matters which occupied his attention was that of the composition of water, and while engaged on this last he had opportunities of familiar intercourse not only with Priestly but with Withering, Keir, Edgeworth, Galton, Darwin, and with his own partner, Boulton, all men above the average for their common interest in scientific inquiries. These gentlemen met at each other's houses at stated intervals, and constituted a philosophic nucleus known as the "Lunar Society," because the time of their meeting was arranged to correspond to the full moon; and this designation earned for them the name of "Lunatics" from an unappreciative butler who had in his turn charge of their creature comforts.

In 1786 Watt and Boulton visited Paris in connection with the installation of some engines and both had a flattering reception in the French capital. Watt describes himself as having been greatly fêted—as having in fact been "drunk from morning to night with Burgundy and undeserved praise."

Returning to England his attention was turned to the defense of his patents now assailed by numerous rivals. Some of the competing engines, as Watt himself describes them, were simply asthmatic "Hornblowers at Radstoke, was obliged to stand still once every ten minutes to snore and snort." "Some were like Evan's mill, which was a gentlemanly mill; it would go when it had nothing to do but it refused to work. After a long and costly litigation the validity of the patents was sustained and he ever afterwards referred to his specifications as "his old and well-tried friends."

With the year 1800 came the expiration of the patent of 1769 as extended by the statute of 1775; and also the dissolution of the original partnership of Boulton and Watt, then of twenty-five years' duration. The contract was renewed in the persons of their sons on whom the business fell.

By this time the business had become so profitable that Watt and his children were provided with a source of independent income, and at the age of 64 the inventor could contemplate the future with a considerable degree of equanimity. Watt himself became stronger, and less oppressed by his bodily infirmities. His spirits became more equable as time went on and his intolerable headaches became fewer.

While resting in his latter days from the severer labors of former years his mind was still occupied with creative work and dwelt on the possibilities of adapting the steam engine to navigation. He lived to know that a steamboat had been used in America, that the British Channel and the Rhine navigated by another; both vessels, the American and British, having been impelled by engines manufactured at Soho. He also made a voyage from Greenock to Rothesay and back again in a steamboat.

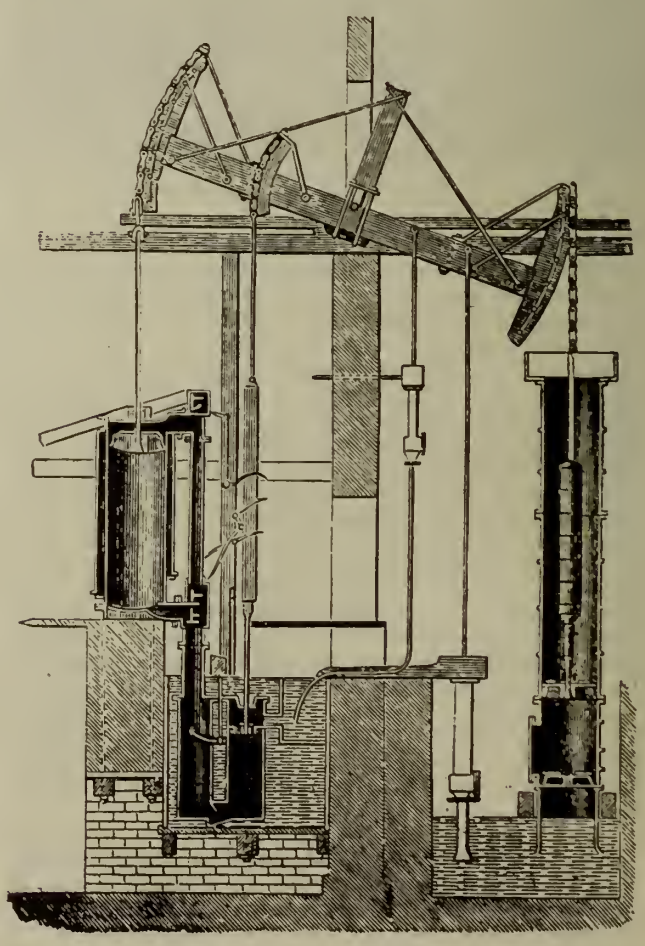
The locomotive, however, was left to a later genius, George Stephenson, for its complete development.

"Some of his idle thoughts" were also turned towards the construction of an arithmetical machine, but he does not appear to have prosecuted his design beyond considering the manner in which he could make it perform multiplication and division. Another of his contrivances, happy in its conception and less difficult of completion, belongs to the 19th century. He was consulted by the proprietors of the Glasgow waterworks as to how they should lay pipes to bring pure spring water across the river Clyde to the company's engines at Dalmarnock; and he devised for this purpose an articulated suction pipe, with joints formed so as to be capable of accommodation to the bottom of the river.

One engrossing occupation, nearly akin to those of his better days, was found in the perfecting of a machine to copy sculpture. The idea of this machine was suggested to him by an implement he had seen in Paris in 1802 where it had been used for tracing and multiplying the dies for medals. The new machine was to do for solid masses and in hard materials what his copying machine had already done for drawings and writings. He himself worked at the machine, set up in the garret of his house assiduously and some of the sculpture still exists. So interested in this work did he become that it is said by one of his biographers that "He even had a touch at the work on Sunday.

Watt was also a great novel-reader, was fond of his garden, fond, too, of a pinch of snuff, but a sufferer from the assiduous proscription of the snuff box by his wife. The second Mrs. Watt was a domestic tyrant to say the least. "On his evenings at home, at a certain hour fixed by Mrs. Watt the door of the dining-room opened, an old servant appeared, and altogether disregarding the greater presence in which he stood, with a few active evolutions swept out at once the fire, the lights and—his master. "And so to bed."

Various persons of note who came into contact with him in the height of his fame and during the closing years of his life have borne witness to the charms of his presence. "His friends," says Lord Jeffrey, speaking of a visit which he paid to Scotland when upwards of eighty, "in that part of the country never saw him more full of intellectual vigor and colloquial animation, never more delightful or more instructing." It was then, also, that Sir Walter Scott, meeting him, "surrounded by a little band of Northern literati," saw and heard "the alert, kind, benevolent old man, his talents and fancy overflowing



WATT'S SINGLE-ACTING PUMPING-ENGINE FOR MINES.

on every subject, with his attention alive to everyone's question, his information at everyone's command."

Campbell, the poet, who saw him later in the beginning of 1819 (he was then 83) describes him as so full of anecdote, that he spent one of the most amusing days with him he ever had. In the autumn of the same year, on the 19th of August, James Watt expired gently and tranquilly at his house at Heathfield. He was buried at Handsworth, and honored afterwards by a public monument in Westminster Abbey.

Boiler Water Treatment

IF you cover a steam pipe with asbestos, magnesia, or other heat-insulating material, you keep the heat in the steam; if you line or coat a boiler tube with scale or other heat-insulating material, you keep the heat out of the boiler water and send it to the stack. By lagging your pipes you save fuel easily. By lining your tubes with scale you waste it continuously and needlessly.

All natural waters contain more or less of this heat-insulating material, partly as suspended matter (such as clay, fine sand, insoluble forms of iron, aluminium, etc.), partly as dissolved matter, such as compounds of calcium, magnesium, sodium, potassium and other mineral salts.

Much of the suspended matter, as well as most of the dissolved matter, may form scale, but the suspended matter may generally be removed by filtration, which will be discussed later.

Dissolved Matter Which Forms Scale

Of the material commonly in solution in boiler waters, the bicarbonates and sulphates of calcium and magnesium are the most important scale formers. Natural waters containing in solution bicarbonate of calcium or magnesium or both exhibit what is called "temporary" or "carbonate" hardness; those containing dissolved calcium or magnesium sulphate or both possess "permanent" or "sulphate" hardness. In the case of the sulphate scale the temperature required to separate it is too high to make its removal by heating alone a practical means of treatment. In the case of water exhibiting carbonate or temporary hardness, great improvement in its properties may be effected by the use of open heaters of the exhaust steam type. As a rule sulphate scale is denser in structure with a higher heat-insulating value than carbonate scale, but the conditions of formation affect this considerably. Where a porous structure permits water to penetrate the scale its heat-insulating effect is greatly reduced.

The Effect of Scale

In many respects the effect of an increasing deposit of scale on the passage of heat through the walls of a boiler tube is very similar to the effect on the passage of water through a tube of continually decreasing bore. In the case of the water tube, the only way to get a uniform volume of water through it in a given time, in spite of its diminishing bore, is continually to increase the pressure in the water. So in the case of a boiler tube covered with a dense scale, the only way to maintain a constant flow of heat from the furnace to the boiler water is to increase the "heat pressure," so to speak—that is, to burn more fuel.

Heat Loss.—The most important effect of scale is due to the fact that in certain forms it is a wonderful heat insulator. Its chemical composition seems to have little to do with its heat-insulating power, the big question being the density or mechanical structure of the scale. A series of experiments by Prof. Schmidt, of the University of Illinois, gave the following results, showing decrease in heat-transfer efficiency of tubes coated with scale of different thickness and composition (see table top of next column).

Character of scale	Thickness Inch	Composition.	Loss of efficiency Per-cent.
Hard	1/50	Mostly carbonate	9
Soft	1/32	Ditto	7
Hard	1/32	Ditto	8
Soft	1/25	Ditto	8
Hard	1/25	Mostly Sulphate	9
Hard	1/20	Ditto	11
Soft	1/16	Ditto	10
Soft	1/16	Mostly carbonate	11
Soft	1/16	Ditto	12
Hard	1/16	Ditto	12
Soft	1/11	Ditto	15
Hard	1/9	Mostly sulphate	16

This, expressed in dollars and cents, means that with a deposit of 1-9 in. of scale, 16 cents of every dollar paid for coal is lost.

The data just given must not be regarded, however, as indicating that the decrease in the heat-carrying capacity of scale-covered tubes can always be calculated with the accuracy that these figures would indicate. The important facts are, though, that the loss is easily prevented, and that the advantages of soft water abundantly justify all expenditure necessary to secure it.

Just what the loss is in any particular case may best be determined by comparing the fuel consumption with clean and then with scale-covered tubes, other operating conditions being kept uniform.

Means of Removing "Scale Formers" From Water.

The methods employed in softening water may be divided into two main classes, (a) those in which the scale-forming property is removed before the water enters the boiler; (b) those in which the softening is effected within the boiler itself by means of so-called "boiler compounds."

As to which one of the two classes of methods should be employed in any particular case, would depend on the size of the plant and on the character of the water to be softened. In the case of waters of abnormal composition, it would frequently be impossible to produce a satisfactory water by either method and a new water supply would be necessary.

It cannot be too strongly emphasized that this question of water treatment is one in which the employment of competent chemical and engineering knowledge is both absolutely necessary and highly profitable, and it would be far wiser to omit all forms of water treatment (involving the use of chemicals) rather than to undertake such without knowing accurately the composition of the water and of the material used to soften it. It is most important to remember that the quality of the water, even when secured from the same source, varies widely from time to time. These variations are not only seasonal and monthly, but daily and even hourly. A condition of excessive concentration of the water after a protracted drought may be changed within an hour to a correspondingly excessive dilution by a summer storm. The result would be to decrease enormously the percentage of dissolved matter and to increase, probably to a much greater degree, the amount of suspended matter.

As a consequence, a prescribed treatment of the water based on its analysis at any particular time might not lead to satisfactory results if applied at some other period.

As an instance of the serious danger of an unintelligent "dosing" of boiler waters may be cited the results of a long series of investigations which have apparently shown that carbonate of soda in solution produces brittleness in boiler steel. Carbonate of soda (soda ash) is used in most water-treating processes, and its unintelligent use may readily lead to a very dangerous condition in a boiler.

When Boiler Compounds May Be Used

Boiler compounds afford a very useful means of boiler-water treatment in plants whose size or value of output would not justify the use of a more expensive method. This would be true of a large percentage of the plants of the country.

In spite of a great variety of trade names, a very large percentage of all boiler compounds consist most largely of carbonate of soda, to which caustic soda is sometimes added, and occasionally phosphate of soda. Starchy materials, and those containing tannin are frequent ingredients. The supposed effect of these last two materials is to coat the particles of precipitated incrusting material and prevent its cohesion into compact scale.

*Technical Paper No. 218, Bureau of Mines, Washington, U.S.A.

Bonus System for Boiler Room Employees

One of the Series on Power Plant Management—This Article Treats of the Bonusing of the Boiler Room Employee and Its Effect Upon Economy in Operation

By ROBERT JUNE, Mechanical Engineer.

THE writer is fortunate in numbering among his friends and acquaintances the chief engineers of a dozen or more of the largest power plants in Canada. Recently he addressed a general letter to these men, asking for a brief description of the bonus systems, if any, used by them as a basis for reward of boiler room employees. To his surprise, these letters were not especially productive of results—most of the replies containing requests for information instead of furnishing it. One answer is typical of the present situation with the majority of the large power plants.

"We try to educate our boiler room men to the fact that power must be produced economically and that this means that high operating efficiencies must be maintained. We instruct our men carefully in their individual and collective duties, pay them high wages and generally give them to understand that we regard them as skilled operatives from whom we have a right to expect high grade results. As an incentive to good work, we post each Monday on the bulletin board in the boiler room the record of overall boiler efficiency for the preceding week.

"While our results in the main are good, we want to improve them. For one thing, we are going to try to separate the percentage of our 24-hour load handled by each of the three shifts. We are doing this on the principle that if one shift handles 50% of the load, and another 30%, and the third 20%, that we should get correspondingly better results from the shifts handling the larger loads. After we have established the proper efficiency for each shift, we are going to put in a bonus system of some sort. We are already working on this, but as you realize, there are a good many angles to the problem, and we should be glad to have any information which you may possess, etc."

This, then, is the situation in many large power plants. They are paying high wages, and trying to educate their men, in some cases by weekly conferences, in conjunction with occasional lectures on various phases of power plant operation. Close supervision of the work of the individual, and personal leadership, evoking a high esprit de corps, are the principal reliance at present. It is considered, however, that these are not enough and that a properly devised bonus system probably offers the necessary supplementary incentive.

Turning now to the smaller power plants, we find that they have been readier to adopt bonus systems. Presumably this is due to the fact that they find it more difficult to provide educational facilities for their men and to exercise close supervision over their work. While the systems used are not elaborate they seem to be effective. The point here worth noting is that the tendency in both large and small plants is increasingly toward the use of bonus systems.

Principles Upon Which Bonus Should Be Based

The term "bonus" may be taken as meaning additional compensation above a fixed amount, based upon net savings effected above a certain minimum through the personal efforts of the recipient. It means that if the operator can reduce the cost per unit of the product he should receive a portion of the savings. As applied to the boiler room a reasonable efficiency, based not alone upon the results previously attained in the particular plant under consideration, but also upon results attained in other power plants of approximately the same size and general characteristics, must be determined upon as a base line or starting point. Before blindly assigning an arbitrary value to performance above this base line, we ought to ascertain with some exactitude the relation of power plant expenses to manufacturing operations as a whole.

Our reason for this is that it will practically always be found that power plant expenses for any business, whether central station, brick and clay, textile, refrigeration, paper, etc., so far as the individual plant is concerned, vary along the line of a fixed curve, depending upon the output of the plant. That is, if the factory as a whole is operated at 100% capacity, power costs will bear a definite relation to the product in terms of pounds,

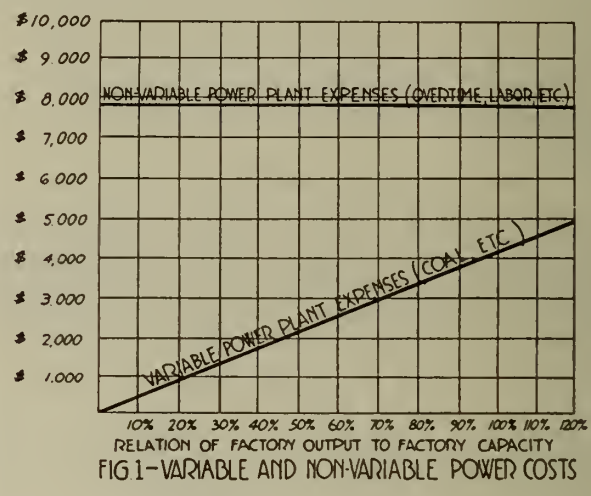


FIG 1—VARIABLE AND NON-VARIABLE POWER COSTS

bushels, yards, tons, or whatever unit the product is measured by. Let us say that our power cost is 10c, or $1.00, or $10.00 per unit, at 100% factory output. If we reduce factory output to 80% we will find that we have a different power cost per unit, say 12c, or $1.20. or $12.00, and if we reduce factory output still further, say to 50% capacity, we will find our cost per unit further increased to say, 15c, or $1.50, or $15.00.

The determination of this curve is not a simple matter. It cannot be done in a week or month, but it is well worth the effort, even if it takes a round dozen of months. The first step is a complete appraisal of the power plant which should include the value of the land and buildings occupied, the complete steam generating equipment with all accessories, the turbines, engines, feed water heaters, condensers, pumps, generators, switchboards, fire pumps, sprinkler systems, all piping and all wiring which apply wholly to the power plant proper, as well as all main lines of pipe and wire on which steam, water and energy are carried to the factory centres.

With our appraisal in hand we at once discover that the reason that our power-cost-per-unit curve is a curve is because power plant costs fall into two divisions—those which do not vary with the volume of product and those which do vary with factory production. As an illustration of the non-variable costs we have interest, depreciation, taxes, and insurance. To these must be added, if the power plant is ready to serve the factory with any amount of power up to 100%, cost of labor, fuel required to bank fires and to keep prime movers turning over, but doing no useful work, and the lubricants, water, ash removal required for this purpose, heat and light for the power plant, etc. These items vary but

little regardless of the factory output—whether it be 30% or 100% capacity.

The variable costs are, of course, coal, equipment maintenance, and a certain amount of general supplies, such as waste, packing, gaskets, etc.

Figure 1 is a typical graph, illustrating the relation of the variable and non-variable cost factors to the volume of production. Figure II is the curve (in this case assumed) resulting from the combination of the variable and non-variable costs. Armed with this curve, the manager is ready to talk business to his chief engineer.

First, be it noted, that in using the curve the manager does not have to be concerned about a single detail of plant operation. He does not have to study boiler efficiencies, engine performance, economical or uneconomical uses of steam, water or electricity. All he needs is the average factory output for a given period, and a summary from the accounting department of the complete costs of power plant operation for the same period. It is a matter of simple division to establish the power costs per unit of output, and to see how it checks with the standard curve. If the power cost is higher than the standard curve indicates it should be, something is wrong and it is up to the chief engineer to find and correct the trouble, and to explain to the manager why it should have occurred; if the actual costs check with the curve, the plant has simply done what it should and no one is entitled to a bonus; if the actual power costs are less than those indicated on the curve for the volume of product, good management and constructive effort has been exercised in the engine and boiler rooms, and the chief engineer and every man under him who has helped in the improvement is entitled to a share in the savings.

At this point it may be well to digress for a moment on the point of responsibility of the chief engineer for all items included in the curve under power costs. Warren E. Lewis, whose engineering record certainly makes him a competent witness, is quite emphatically of the opinion that the chief engineer should be held wholly responsible. He states:

"Some engineers have argued that it (the curve) is not a fair basis of payment, that all that the operating engineer can do is to make steam efficiently, run his engines, pumps, heaters, etc., as well as he knows how, and that he has no control of the situation beyond his department. That is partly true and partly not true. The functions of the chief engineer should extend beyond the confines of the engine and boiler rooms. He should spend at least one-third of his time around the plant, and he should have an inspector going around the plant continually watching out for improper use of power, light, steam, etc. The chief engineer should be directly concerned in seeing that the process machinery is maintained in an efficient condition. This is particularly true with regard to apparatus that uses steam in any form. If we include in the power plant all the equipment which in any way affects the use of fuel, it becomes a comparatively simple matter to place upon the chief engineer the responsibility for the efficiency of the entire power-making and power-using equipment, and for its cost per unit of production."

Now, getting back to the bonus, let us suppose that the management decides to set apart, say 33 1-3 per cent. of the savings effected, to be distributed as a bonus. Clearly, the chief engineer, individually, is entitled to a certain portion of this, and this portion should be determined by the manager. The proportioning of the remainder among the various power plant employees should be practically in the hands of the chief engineer for the reason that he is in constant touch with the work of the various individuals.

That the just proportionment of the bonus among the various individuals will cause the chief engineer some serious study is not denied. It is important, however, that individual rewards be established, and that the bonus be not simply divided among the men on a pro-rata basis or with reference to their respective wages. The final results are due to the combined efforts of all of the men, and are beyond the control of any one man.

It is necessary, therefore, to judge each man on the basis of his performance of his individual task. If boiler efficiency falls off it may be due to improper firing, in which case the fireman should be penalized, or it may be due to failure to keep the boiler clean, free from soot and scale, in which case the man who does the cleaning should lose all or a part of his bonus, or again the loss in efficiency may be due to leaky boiler settings, a condition clearly outside of the jurisdiction of the fireman, and clearly up to the boiler room foreman.

This principle of individual responsibility applies all along the line. For instance, if a new grade of coal is brought into the plant and the chief's assistant engineers do not make it their business to see that the firemen are fully instructed regarding the proper method of firing, they are guilty of a breach of duty for which they should suffer. The engineers are, of course, responsible for permitting radiation losses to continue because of failure to insulate pipes, and for failure to correct leaky valves, traps, worn gaskets, etc. The engineers or boiler room foreman must be held responsible for economical operation in cutting boilers in or off the line, operating them at economical ratings, and banking or killing fires.

When the bonus is not earned by a particular individual it may be due to his own fault in not following instructions, to faulty maintenance, making compliance with instructions impossible, or to faulty supplies. With so many angles to the problem, it is evident that close inspection and constant supervision of the work of the individual is absolutely necessary if material reductions in power plant costs are to be made.

It is realized that the program here outlined may seem elaborate. The small plant operator, in particular, may think it complicated, but it is precisely in the small plant that astonishingly good results can be attained. Admitting elaborateness, this basis of bonus is certainly thoroughgoing. To the writer's mind there is no point whatever to paying firemen a bonus for high CO_2, or for high boiler efficiency, if no corresponding effort is made to see that the steam, when produced, is utilized without preventable waste.

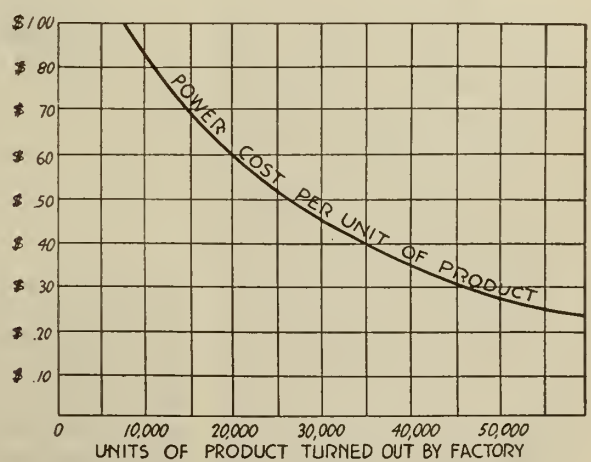

FIG. 2. POWER COST PER UNIT OF PRODUCT

Railway Dynamometers and Their Use

The Following Article Gives Some Interesting Details Relating to That Branch of Steam Engineering Identified With Locomotion and Takes Up Some of the Underlying Principles of Traction

By G. S. BALDWIN

FREIGHT is the dividend-paying business of all railroads and therefore it is of the first importance to know exactly how much tonnage each class of locomotive will haul over every division. It is just as expensive to overload an engine and have it stalling all over the road as it is to let it travel light. This is, of course, assuming that there is an evenly balanced flow of traffic in both directions. But this, which would be an ideal condition, does not usually hold good, particularly in Canada, where the preponderance of traffic is westbound for about six months and eastbound for the other six. In that case it is all the more important that a locomotive shall take her full load in the direction of traffic, since she will possibly have to make the return trip 20 or 30 per cent. light, or even with a "caboose hop."

A locomotive is rated as to the tractive effort she will exert on the drawbar, and to facilitate tonnage rating, this is usually expressed in percentage. A tractive effort of 20,000 lbs. is called 100 per cent., and an engine which should develop 30,000 lbs. is called a 150 per cent. engine, and so on.

The tractive effort is usually calculated as follows:

$$E = \frac{C^2 \times s \times p}{d}$$

when

E = the tractive effort in lbs.; c = the diameter of the cylinder in inches; s = the stroke in inches; d = the diameter of the driving wheels in inches, and p = the mean effective boiler pressure in pounds per square inch.

Of course the effective boiler pressure will vary considerably at different speeds, since the faster the engine travels the earlier the cut-off will be, and consequently the lower the effective pressure. But as we are considering the maximum load an engine will haul over heavy grades we are dealing with slow speeds. In fact engines usually develop their greatest tractive effort at a speed in miles per hour equal to between one-eighth and one-ninth of the diameter of their driving wheels. For instance, an engine with a 63 in. wheel will develop her greatest pull between seven and eight miles per hour, and an engine with a 54 in. wheel between six and seven miles per hour. We are therefore pretty near the mark in assuming the mean boiler pressure to be 85 per cent. of the maximum pressure.

Take an engine with 28 in. cylinders, 21 in. stroke, 63 in. driving wheels, and 180 lbs. of steam, and we get:

$$E = \frac{28 \times 28 \times 21 \times 157}{63} = 41.039 \text{ lbs.},$$

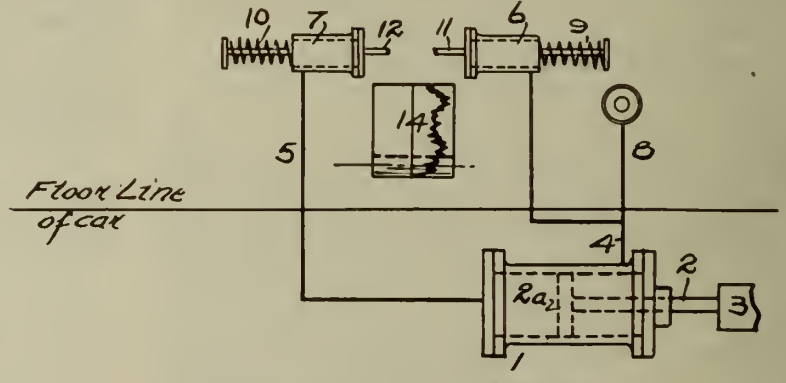
or 205 per cent.

The ruling grade over a division, except in mountainous country is usually .4 per cent., and if the line and surface of the track is in good condition and there is a good length of straight track where the maximum effort has to be exerted it will require something like 17.7 lbs. to move each ton of load. In which case the engine above referred to could be expected to haul in the neighborhood of 2,316 tons.

Now you will say if you can figure out so exactly what load can be hauled, why go to the trouble and expense of making dynamometer tests at all? For the following reasons: Firstly, though the track profile may show a .4 per cent. grade, the road may not. There may be a curve on which all trains carrying full rating stall because sufficient allowance in the way of grade reduction has not been made. On a slight curve it is usually found that the locomotive has an additional resistance of 1.5 lbs. per ton of its own weight for each degree of curve, which dynamometer records will not show, because only the actual pull on the drawbar can be indicated in that way, and the train will show an additional resistance of about .751 lbs. per ton for each degree of curve. The radius of any degree of railroad curve is 5729.65 feet divided by the number of degrees, for instance, a 10 degree curve has a radius of 572.965 feet. On a single track road, if a curve is at all sharp the outer rail is raised to take care of fast moving traffic in the opposite direction, in which case there would be a considerably greater resistance than that mentioned above. Consequently curves on a grade are usually compensated, that is a reduction is made in the climb to offset the extra work necessary to get round them. This is frequently taken at .02 per cent. for each degree of curve.

Other points must be taken into consideration also. For instance, in very exposed places a strong wind blowing across the track will have a marked effect. Or if a station is located near a heavy piece of road so that trains do not get a swing on before starting to climb they may get into difficulties. In short, there are so many local conditions which govern each division that, without making a test it is almost impossible to put on a fair rating. Of course tests can be made without a dynamometer, but in that case it is impossible to know whether the engine developed her rated drawbar pull before she turned round and counted the cars.

Before starting on a test the first thing to do is to ascertain the weight of the train, which is made up of two things, the tare weight of the cars and the weight of their contents. Roughly speaking the tare should be one-third and the contents two-thirds of a fully loaded train. Supposing the train to be 2,250 tons, and made up of loads, the consist would show approximately 1,500 tons contents and 750 tons tare. On the other hand, if there were a number of empties and partially loaded cars we might find that the contents only came to 750 tons and the tare 1,500 tons. Now obviously this would be a considerably longer train and a far harder one to pull, consequently an allowance is added to the sum of the tare and contents in all cases where the contents is less than twice the tare. A frequent method of figuring the allowance is as follows: Deduct half the contents from the tare and add 10 per cent. of this amount to the tonnage. In the case mentioned above the total tonnage would figure like this:



DIAGRAMATIC VIEW OF DYNAMOMETER.

	Tons
Tare	1,500
Contents	750
Allowance	112
Total tonnage	2,362

The dynamometer is arranged immediately behind the tender and consists of a cylinder, 1, having a piston-rod, 2, connected to the drawbar, 3, which is coupled in the ordinary way to the tender drawbar. From the ends of the cylinder, 1, which is filled with oil, pipes 4 and 5 lead up to the recording cylinders 6 and 7 respectively, and a pressure gauge 8 is also provided on the pipe 4. Behind the cylinders 4 and 5 springs 9 and 10 are so arranged that they must be compressed as the pistons 11 and 12 move forward.

The whole load of the train is on the tender drawbar, and is therefore carried by the piston 2a in the oil-filled cylinder, 1. This load is evenly distributed over the oil, which communicates the pressure to the gauge 8 and the cylinder 6.

Supposing the bore of the cylinder is 11.75 in. and the piston rod, 2, is 3.28 in. in diameter, the effective area of the oil is 100 square inches. Therefore, when a pull of 40,000 lbs. is exerted there will be a pressure of 400 lbs. per square inch on the oil. This pressure is communicated through the pipe, 4, to the gauge 8, and the recording cylinder 6. If the latter has a bore of 1.187 in., and the piston rod, 11, is .370 in. in diameter, the effective area of the cylinder will be 1 sq. in. The springs 9 and 10 are calibrated to say 100 lbs. to the inch, and both the cylinders and the springs must be of sufficient length to take care of the maximum pressure that may be exerted through the oil. With a pressure of 400 lbs. per sq. in. operating in the cylinder, 6, the pressure will be 400 lbs., acting against the springs, on account of the effective area of the said cylinder being one sq. in. Consequently the piston and rod, 11, will move forward 4 in. against the 100 lb. spring. Usually for recording cylinder pressures of from 400 to 600 lbs., spring calibrated to 150 lbs. are used.

A suitable pantagraph arm system must be connected to the near ends of the piston rods 11 and 12, so that an automatic record may be made on a sheet, 14, which is fed under the pen at so many feet to the mile, the drive being obtained direct from the car axle.

The object of the pressure gauge is to check up the oil pressure when making a scale from which to read the records; the scale is usually divided off into 500 lbs., up to 60,000 lbs. of whatever load is anticipated. A second pen draws a constant datum line on which the pen in the pantagraph arm also rests when no pull is being exerted on the drawbar.

When reading compression on the oil cylinder it must be remembered that the scale is only approximate in that case as the effective area is greater on account of there being no piston rod on that side of the cylinder. In the case in question the effective area would be 108.43 square inches against 100 square inches on the opposite side of the piston, but if these readings are required it is quite easy to make another scale on which the graduations would be slightly larger.

Any suitable arrangement of piping to and from a pump is also installed so that oil may be pumped from one side of the cylinder to the other, as for safety's sake it is always advisable to keep the main piston about the centre of the cylinder. And the piping is also so arranged that fresh oil may be pumped into either end of the cylinder, or so that pressure may be put on the line, 4, for making or checking up scales.

THE FRACTURE OF A FURNACE WHILE ITS BULGE WAS BEING SET BACK

Expertness in setting back bulged furnaces has improved very much of late. This is probably partly due to the increasing number of cases, due to war conditions, and partly to the difficulty of obtaining plates for replacing damaged furnaces. One of two cases which ended in failure should, therefore, prove of interest as it indicates the dangers to be avoided. When the bulges are relatively slight they are usually set back cold, but when deep they are heated by fires, usually by Wells lamps, set back hot and finished-off cold. In one case during the cold finishing-off process on a bulged furnace, a circular piece of plate measuring 10 in. diam. burst out of the furnace plate. The nature of the fractured surface left no doubt that the fracture was an instantaneous one, except over a length of about 1½ in. where the edges of the plate were slightly bent. This curious piece of plate is to be seen in our museum. The following is the most probable explanation of this mishap: In 1886 a paper was read before a meeting of the Institute of Civil Engineers in which a large number of experiments were discussed which proved clearly that both wrought iron and mild steel have a common critical temperature, usually called blue heat, because bright steel or iron changes color through straw to purple or blue, at which temperature the material, although softer than when cold, is in a rotten condition and usually breaks if bent. If the bending be stopped before either breakages or cracks occur, and if the sample be put aside for a short period and the bending continued, or the sample straightened, then it is almost sure to break. Other mechanical manipulations while the steel is "blue hot" will also impart to it permanent brittleness. Thus on the occasion of the reading of the above paper, a bar of mild steel about 1 in. wide and ½ in. thick had been bent double at one end while cold in order to demonstrate its ductility or toughness, the other end of the bar had been polished and warmed between heaters until it commenced to change color from straw to purple and blue. While at this temperature it was placed under a steam hammer and reduced in thickness from ½ in. to ⅜ in., and was then laid aside for the meeting, at the end of which it was struck against a small anvil and broke in two. The ends of this sample were preserved and retested after waiting about 30 years, when they were still found to be as brittle as at first. Evidently age has no beneficial effect on improperly worked steel; it can only be restored to its originally good condition by annealing. These experiments explain why the application of heaters to flanges, and other parts of boilers which have to be slightly bent, very often leads to cracks, which are called mysterious, because the true cause, the heaters, are either not mentioned or have been forgotten. Now what had happened in the present furnace mishap was very simple. The bulge had been heated by a Wells lamp. The centre was said to have been red hot, and there must therefore have been a circular zone over which the temperature was a "blue heat" during the time that the bulge was being pressed back. The setting back appeared to be perfectly satisfactory, but next day it was thought that a further improvement could be effected by re-applying ram pressure on the cold plate, with the result that the plate fractured in a circular line through the zone which had been made permanently brittle by being bent while "blue hot." It is therefore evident that in future, if furnace bulges have to be heated before being set back, they should be re-heated after they have been set back.

The annual output of thirteen billion gallons of petroleum in the United States consists of 1,800,000,000 gallons of kerosene and about twice as much gasoline, the remainder being gas oil, distillate and light and heavy residuals.

Where great power is applied slowly, particularly when space is at a premium, the worm-and-wheel drive is seen at its best. Another advantage of this type of drive is the ease with which it can be kept oiled. Perhaps greased would be a better term because the worm frequently works in grease. The whole drive is usually enclosed in a grease-tight box, though which passes the driving shaft.

* * *

In a certain plant the technical magazines which are received are first read by the engineers in the office. They are then placed in a box made especially for this purpose, at the employees' entrance. Any worker may take one at a time home, and after reading it, return it to the box so that other employees may read it. This scheme is worthy of more general application.

* * * *

The elephant has what a dentist calls "magazine gun teeth" because of the curious fact that when the big pachyderm wears off a front tooth it is replaced by the one tooth just behind it, the whole row moving up a tooth. It is said this takes place continually, so Jumbo always is guaranteed a set of teeth, no matter how many he wears out.

Resuscitation from Electrical Shock

The Commission on Resuscitation From Electrical Shock Have Recently Revised the Rules for the Carrying on of Resuscitation and in View of the Importance of This Work They Are Here Reprinted in Full

The prone-pressure method of artificial respiration is applicable to resuscitation from electrical shock and all cases of suspended respiration due to drowning, inhalation of gas, smoke or fumes or to other causes.

AN accidental electrical shock usually does not kill at once, but may only stun the victim and for a while stop the breathing.

The shock is not likely to be immediately fatal, because:

(a) The conductors may make only a brief and imperfect contact with the body.

(b) The skin, unless it is damp with perspiration or wet, offers some resistance to the current.

The life of the victim depends upon the prompt and continued use of artificial respiration. The reasons for this are:

(a) The body continuously depends on an exchange of air, as shown by the fact that we must breathe in and out about fifteen times a minute.

(b) If the body is not thus repeatedly supplied with air, suffocation occurs.

(c) Persons whose breathing has been stopped by electrical shock have been reported restored after artificial respiration has been continued for approximately four hours, and the treatment should be continuously applied until rigor mortis (stiffening of the body due to death) sets in.

The Schafer, or "prone pressure" method of artificial respiration, slightly modified, is illustrated and described in the following resuscitation rules. The advantages of this method are:

(a) It is immediately available.

(b) Easy performance; no apparatus and little muscular exertion required.

(c) Larger ventilation of the lungs than by the supine method.

(d) Simplicity, the operator makes no complex motions and readily learns the method.

(e) No trouble from the tongue falling back into the air passage. The first impulse is expiration, and any foreign substance in the mouth or air passage will likely be expelled.

(f) No risk or injury to the liver or ribs if the method is executed with proper care.

Aid can be rendered best by one who has studied the rules and has learned them by practice on a volunteer subject.

Instructions for Resuscitation

Follow these instructions even if victim appears dead.

I.—Free the Victim From the Circuit Immediately

1. Quickly release the victim from the current, being very careful to avoid receiving a shock. Use any dry non-conductor (rubber gloves, clothing, wood, rope, etc.) to move the victim or the conductor. Beware of using metal or any moist material. If both the victim's hands are grasping live conductors endeavor to free them one at a time. If necessary shut off current.

Begin at once to get the subject to breathe (resuscitation) for a moment of delay is serious. Use "Prone Pressure Method" for four (4) hours if necessary, or until a doctor has advised that rigor mortis has set in.

Observe Following Precautions

(a) The victim's loose clothing, if dry, may be used to pull him away; do not touch the soles or heels of his shoes while he remains in contact—the nails are dangerous. If this is impossible, use rubber gloves, a dry coat, a dry rope, a dry stick or board, or any other dry non-conductor to move either the victim or the conductor, so as to break the electrical contact.

(b) If the bare skin of the victim must be touched by your hands, be sure to cover them with rubber gloves, mackintosh, rubber sheeting or dry cloth, or stand on a dry board or on some other dry insulating surface. If possible, use only one hand.

If the man receives a shock while on a pole, first see that his belt is secure around the pole, if possible above cross-arm, so victim will not fall, then break the current. Pass a hand-line under his arms, preferably through his body belt, securely knot it, and pass the end of the line over the first cross-arm above the victim. If you are alone, pass the line once around this cross-arm. If you are not alone, drop the line to those at the base of the pole. As soon as the rope is taut, free the victim's safety belt and spurs and descend the pole, guiding the victim. When the victim is about three feet from the ground, lower rapidly so that the victim's feet hit the ground hard.

2. Open the nearest switch, if that is the quickest way to break the circuit.

3. If necessary to cut a live wire, use an ax or a hatchet with a dry wooden handle, turning your face away to protect it from electrical flash.

II.—Attend Instantly to Victim's Breathing

1. As soon as the victim is clear of the live conductor, quickly feel with your finger in his mouth and throat and remove any foreign body (tobacco, false teeth, etc.) If the mouth is tight shut, pay no attention to the above-mentioned instructions until later, but immediately begin ressucitation. The patient will breathe through his nose, and after resuscitation has been carried on a short time the jaws will probably relax, and any foreign substance in the mouth can then be removed. Do not stop to loosen the patient's clothing; every moment of delay is serious.

FIG. 1.

2. Lay the patient on his belly, one arm extended directly overhead, the other arm bent at elbow and with the face resting on hand or forearm so that the nose and mouth are free for breathing. (See Fig. 1.)

3. Kneel, straddling the patient's hips, with the knees just below the patient's hip bones or opening of pants pockets. Place the palms of the hands on the small of the back with fingers resting on the ribs, the little finger just touching the lowest rib, the thumb alongside of the fingers, the tips of the fingers just out of sight. (See Fig. 1.)

4. With arms held straight, swing forward slowly so that the weight of your body is gradually brought to bear upon the subject (see Fig. 2). This operation, which should take from two to three seconds, must not be violent—internal organs may be injured. The lower part of the chest and also the abdomen are thus compressed, and air is forced out of the lungs, the diaphragm is kept i nnatural motion, other organs are massaged and the circulation of the blood accelerated.

5. Now immediately swing backward so as to completely remove the pressure, thus returning to the position shown in Fig. 3. Through their elasticity, the chest walls expand, and the pressure being removed the diaphragm descends and the lungs are thus supplied with fresh air.

6. After two seconds swing forward again. Thus repeat deliberately twelve to fifteen times a minute the double movement of compression and release—a complete respiration in four or five seconds. If a watch or clock is not visible, follow the natural rate of your own deep breathing, the proper rate may be determined by counting—swinging forward with each expiration and backward with each inspiration.

7. As soon as this artificial respiration has been started, and while it is being continued, an assistant should loosen any tight clothing about the patient's neck, chest or waist. **(Keep the patient warm.)** Place ammonia near the nose, determining safe distance by first trying how near it may be held to your own. Then the assistant should hit the patient's shoe heels about twenty times with a stick, and repeat this operation every five minutes, until breathing commences. Do not give any liquids whatever by mouth until the patient is fully conscious.

8. Continue artificial respiration without interruption (if necessary for four hours) until natural breathing is restored. Cases are on record of success after three and one-half hours of effort. The ordinary tests for death are not conclusive in cases of electric shock and doctors must be so advised by you, if necessary.

9. When the patient revives he should be kept prone (lying down)—and not allowed to get up or be raised under any consideration unless on the advice of a doctor. If the doctor has not arrived by the time the patient has revived, he should be given some stimulant, such as one teaspoonful of aromatic spirits of ammonia in a small glass of water, or a drink of hot ginger tea or coffee.

The patient should then have any other injuries attended to and be kept warm, being placed in the most comfortable position.

10. Resuscitation should be carried on at the nearest possible point to where the patient received his injuries. He should not be moved from this point until he is breathing normally of his own volition, and then moved only in a lying position. Should it be necessary, due to extreme weather conditions, etc., to move the patient before he is breathing normally, he should be kept in a prone position and placed upon a hard surface (door or shutter) or on the floor of a conveyance, resuscitation being carried on during the time that he is being moved.

FIG. 2.

11. A brief return of spontaneous respiration is not a certain indication for terminating the treatment. Not infrequently the patient, after a temporary recovery of respiration, stops breathing again. The patient must be watched, and, if normal breathing stops, artificial respiration should be resumed at once.

III.—Send for a Doctor

If other persons are present when an accident occurs, send one of them for a doctor without a moment's delay. If alone with the patient, do not neglect the immediate and continued resuscitation of the patient for at least one hour before calling a doctor to assist in further resuscitation efforts.

A published, up-to-date list of doctors posted by the company is recommended.

IV.—First Care of Burns

When natural respiration has been restored, burns, if serious, should be immediately attended to while waiting for the doctor to arrive.

A raw or blistered surface should be protected from the air. If clothing sticks, do not peel it off—cut around it. The adherent cloth, or a dressing of cotton or other soft material applied to the burned surface, should be saturated with picric acid (0.5 per cent.). If this is not at hand, use a solution of baking soda (one teaspoonful to a pint of water), or the wound may be coated with a paste of flour and water, or it may be protected with vaseline, carron oil, olive oil, castor oil or machine oil, if clean. Cover the dressing with cotton, gauze, lint, clean waste, clean handkerchief, or other soft cloth, held tightly in place by a bandage.

The same coverings should be lightly bandaged over a dry, charred burn, but without wetting the burned region or applying oil to it.

Do not open blisters.

An electric-heating system which utilizes power that would otherwise go to waste has been installed in a school in a southern European city. The existing hot-water pipes and radiators are connected with a well-insulated water tank of 1,300-gal. capacity. In this reservoir electric resistances are built and at night are supplied with current which raises the water to well above the boiling point. The cost of the current is low because the water power used to produce it normally would go to waste. During the day the hot water is allowed to circulate through the radiators, its volume being sufficient to warm the rooms without using more current. The desired temperature is maintained by a thermostat.

FIG. 3.

Is Your Heating Plant Ready for the Winter?

While the Weather is Warm is the Time to Prepare for the Cold Time Coming—Cold Rooms in a Factory Are a Cause of Dissatisfaction to All Concerned

By T. H. FENNER, Associate Editor

IN that locality which is popularly supposed to be paved with good intentions, we are led to believe that no trouble is ever experienced with the heating arrangements. It is also an attribute af fallible human nature that once the immediate incentive of the said paving material has disappeared, action is delayed in favor of some more pressing need, till the recurring season brings along the old troubles, and a crop of vain regrets. All of which is merely a way of saying that to avoid six months of misery in the winter, a few days or weeks should be devoted in the summer to a thorough examination of the heating arrangements.

There are few things that lead to more lost time and bitter recriminations than the failure of the heating system to properly function at the required time. Workmen coming in to a cold room first thing in the morning are usually disgruntled for the remainder of the day, and are prone to stand around the shop, with their hands in their pockets, calling down anathema on the engineering department, rather than attempt to forget the temperature by an assiduous attention to the job in hand. In many cases they are not to be blamed, for a man who is engaged on monotonous repetition work, which entails but little bodily activity, is usually supersensitive to uncomfortable shop conditions. Furthermore, the plant superintendent, who has to sit in an office where the temperature is around 50 degrees, is not disposed to kindly feelings towards his chief engineer. The latter may not be entirely to blame, as oftentimes lack of sufficient or competent help has caused him to delay the necessary overhauling until an unusually early cold snap brings down trouble on his prematurely gray head.

A winter season such as we had in Canada in 1918-19 did not strain the capacity of the heating plant over-much, and the early spring, followed by the gloriously warm summer, was likely to dispel all thoughts of heating systems from the minds of the engineering staff, but there have been some chilly mornings and evenings lately which serve as a sharp reminder that our summers are short. If not already done now is the time for a sharp and systematic campaign, started at the exhaust line and carried through the factory.

The Right Time To Do It

The proper time to overhaul the heating system is the early summer, just as soon as one can feel that there is no chance of the system being required again that season. All its most obvious needs are, or should be, fresh in the mind then, and the unpleasant remarks caused by them still rankling in the breast. That main reducing valve, for instance, that requires a new diaphragm, the leaky joints in awkward corners of the basement, the vacuum valves which have ceased to justify their existence, and the countless other small things that have had to be neglected for the time being. Small things in themselves, but what a cause of misery in the aggregate.

Perhaps there has been no lack of heat in the factory, but the heat has only been maintained by the expenditure of a totally disproportionate amount of coal or else there has been both a lack of heat in certain sections, as well as a large coal bill. In the small and compactly arranged factory it may not have been very bad, but in the plant that covers a large area of ground, with the heating done from a central plant, the waste may be enormous.

Two Points to be Considered

There are two things to be taken into account. The heating system itself and the state of the buildings. There is little use in having a perfect heating system if there are ½-inch openings around window frames, door jambs, pipe entrances to buildings. The chief engineer should send his foreman bricklayer or painter or go himself if possible, and make a systematic inspection of the buildings, taking careful notes of all places where the cold winds can find entrance, and then take effectual steps to stop them. A little spring yarn caulked tightly into the spaces between window frame and brick work will work wonders in the way of comfort and saving of fuel. Where roofs are built with lanterns take a good look at the joint of roof and lantern, and see that there is no open space under the flashing, and that the flashing itself is in good repair. Count up the broken panes of glass and order the required quantity immediately so that it can be all replaced before the summer is over. There will be quite enough work to be done on building exteriors to keep a man or two busily engaged all summer, and there is no one more vitally interested in having this work done than the chief engineer. Every bit of cold air that enters a building by unauthorized inlets has to be heated up, and it all requires some of his dearly bought b.t.u.'s. Furthermore, a building that is reasonably tight will retain the heat for the better part of the night, when the main engines are stopped, and makes less demands on the live steam.

Coming to the heating plant itself, there is ample scope for useful work to be done. In a large factory there are miles of coils, thousands of feet of main feeders, risers and returns, and hundreds of steam and thermostatic valves, outside of the engine room altogether. The majority of plants using exhaust steam for heating are equipped with a vacuum return system, the returns being delivered to the feed water heater, and thence to the boiler. Where feed water has to be paid for, the more water that is reclaimed from the heating system the less has to be paid for. But it must be free from oil, and it is also necessary to have the oil extracted from the exhaust before it enters the steam heating system, otherwise it will coat the coils and form an excellent non-conductor. Therefore, the oil extractor on the main exhaust line should be thoroughly cleaned, and the trap or other drainage arrangements examined and put in good shape. The vacuum pump should next be overhauled, both steam and water ends, and rods turned up if necessary. The suction and discharge valve plates should be taken out, and if the valve seats are worn unevenly, they can be put on the shaper and faced up. Failing this, they should be faced up with a surface board and file and scraper. Overhaul the valve springs and valves, pack the plunger, and see that the pump barrel liner is not worn in the middle. If it is have it bored out. Once the pump is as perfect as possible you are in a position to start testing out your system. The usual arrangement of piping is a main carried from power house to factory basement, and individual branches carried to different sections of the building. The return branches are brought back to a return main, which is connected to the suction of the vacuum pump. The function of the vacuum pump is two-fold. It has to deliver the condensation from the returns to the feed heater, and also maintain a difference of pressure between the main exhaust and the return system, to ensure a circulation of steam through all the coils. If the pump is not doing its duty, there will be an increase of back pressure on the engine, and the heating system will be filled with water, the result being more fuel consumed, and a cold factory, while the heat that should be going into the building will be carried up the atmospheric exhaust to the open air. If there are leaks in the system anywhere the pump will be drawing air into the returns instead of maintaining a vacuum. Air leaks should be eliminated as far as practicable. Now shut off every branch valve, both steam and return, leaving only the length of the main return open to the pump. Better still blank off the

return branches in case there may be leaky valves on the branch where it joins the main. Blank off the water connection to the small condenser on the suction pipe and start the pump. You should get a vacuum immediately, and if your pump is in good shape you will be able to drain from 20 to 24 inches on the gauge. Now stop the pump, and if the length you are testing is tight, the vacuum will be maintained for a considerable time, say 10 to 15 minutes. If it disappears in three or four minutes there is a leak, which must be stopped. Now take the blank flange from one branch and connect it to the return main. This branch may carry four or more coils. Blank these coils off at the steam end, one at a time, and take the thermostatic valve out of the return end, and get the vacuum again. If it does not hold, take a candle, keeping the pump running, and try the flame at every joint till the leak is discovered. Try every coil in this way, till you are morally certain that your return system is airtight.

Then comes the steam side. You can test this out by taking out the thermostatic valves and pulling the vacuum right through, but a more convenient way is to blank your main, one section at a time, and attach a small branch from the air compressor to it. Pump up about five pounds pressure, and see how long it remains. You will soon discover the leak and can remedy each section as you go along. There remains one very important feature, the thermostatic valves. There are various types of these, some being controlled by the expansion and contraction of a volatile liquid and others by the expansion and contraction of a carbon. Those operated by the liquid usually are non-adjustable, but the carbon ones are, and if not adjusted correctly will allow steam to blow right through the coil. Now the latent heat of steam is much more than the sensible heat, but if the steam is not held in the coil till condensed, the latent heat will be given out where it is not wanted, in the return pipe. Therefore, the thermostatic valve must be adjusted so that it will remain closed unless surrounded by water. The best way to ensure this is to disconnect the union on the return side of the valve and then put steam in the coil. If steam blows through screw the carbon body down a little by the screw provided in the top, until the steam stops. Then note if it opens to let the condensation out. It should open and shut precisely as a steam trap does.

When the system is in operation send a man around to every coil at least once a week, to see that valve spindles are tight and nothing leaking on the coil itself.

These precautions will well repay the work involved by the peace and comfort obtained. A factory uniformly warm in every department, Monday morning as well as Saturday noon, will produce more and better work than one in which these conditions are not maintained.

TEST FOR GROUNDS ON INTERIOR WIRING

By James V. Shannon

(Copyright. All rights reserved)

A NUMBER of public utility companies follow the practice of testing for grounds on the interior-wiring circuit each time the watt-hour meter at the installation is tested. The method which is, usually, followed, is that shown in the diagram Fig. 1. At I is indicated the interior installation. The secondary circuit is, usually, as shown at Gp, grounded. An accidental ground, Ga, is indicated in the interior wiring.

Now, to test for this ground, Ga, the meter tester removes the house leads from the meter and twists them together as shown at T. Then he connects up his test lamp, L, between the live side of the line and T. If the ground at Ga is of sufficiently low resistance his test lamp will light. Sometimes grounds on interior wiring are of such high resistance that they will not light a test lamp. In such a case a rotating standard (a watt-hour meter-testing instrument) is inserted as shown at R, Fig. 2-I. By following the directions which accompany the rotating standard, it is possible, by counting the number of revolutions which the pointer of the instrument makes in a certain period of time, to determine the watts power consumed by the ground. Then the voltage of the circuit being known, the current flowing may be ascertained and from the current and voltage values the resistance of the ground in ohms can be computed.

The above-described methods apply particularly to alternating-current installations. For direct-current work a millivoltmeter can be used somewhat as indicated in Fig. 2-II. The resistance of the ground on the interior wiring circuit can be computed in ohms by following the usual method for ascertaining the value of a high resistance with the millivoltmeter.

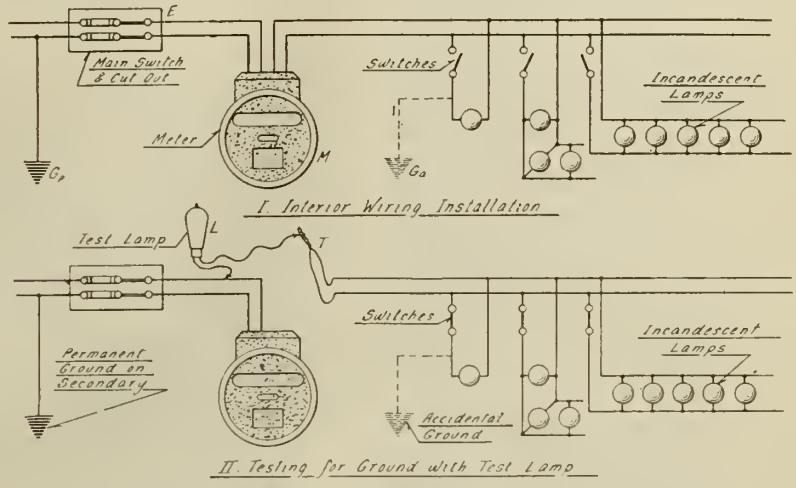

FIG. 1—TESTING FOR GROUNDS WITH TEST LAMPS.

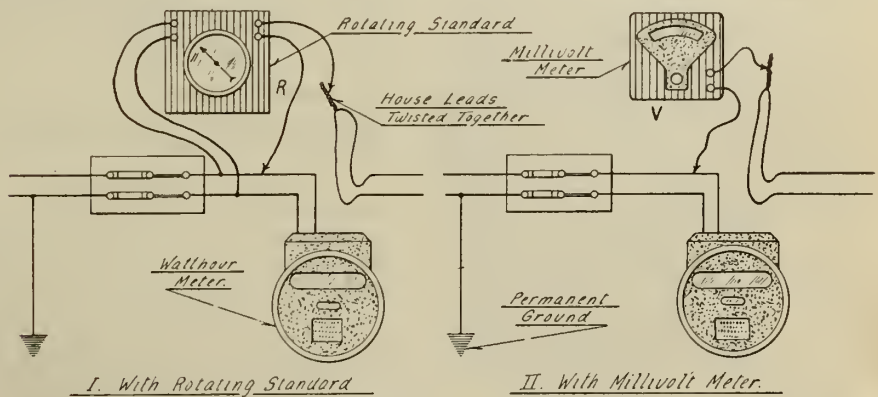

FIG. 2—APPLICATION OF ROTATING STANDARD AND MILLI-VOLTMETER.

The Johns-Pratt Company, Hartford, Conn., cordially invites all members of the N.A.S.E., as well as all superintendents, master mechanics and operating engineers to visit booths No. 221 and 222 during the coming exhibition.

The use of a cold chisel by anyone inexperienced with it usually results in the hammer occasionally striking the hand instead of the chisel, with disastrous results. For the use of beginners, and possibly some of the older workmen who occasionally fail to hit the chisel directly on the head, it will be helpful to cut out a disk of old leather belting, making a hole of the proper size in the centre, and mount it on the end of the chisel to break the force of any misdirected blow.

Central Station Heating in Detroit

The Author in a Paper Read Before the American Society of Mechanical Engineers in Detroit Describes a Successful Central Station Heating Installation in Detroit

By J. H. WALKER

ONE of the natural results of the grouping together of human beings in civilized communities is the existence, in our cities, of central plants for the generation and distribution of heat to surrounding buildings. The advantages of central heating service to the user, over the alternative of operating a heating plant in his own building, are comparable to those accompanying any other public service. To the community also a properly operated central heating plant is a distinct asset, commercially and economically.

The Utilization of Exhaust Heat

The heat carried away by the condensing water in the central electric stations of the United States, equivalent to about 60 per cent. of the total fuel burned by them, is one of the more obvious, although not by any means the greatest waste, of the country's resources. Like many other similar losses this one exists, not because its reduction is theoretically impossible, but because it is seldom commercially practicable. But although commercial considerations have always dictated certain practices in the utilization of fuel and will continue to do so in the future, the increasing cost of coal and the present impulse towards its conservation now direct attention to some of the fundamental problems involved.

This great quantity of heat, rejected at low temperature from the generating units, may be considered as a by-product of electricity supply and as such its rate of production will depend upon the rate of production of electricity, the primary product. The complete utilization of any by-product becomes possible only when an outlet for it exists or can be created. Moreover, since neither electrical energy nor heat can be stored to any great extent, it is necessary for the complete recovery of this by-product that the demand for it be equivalent, hour by hour, and day by day, to the rate of electricity supply. The warming of the interior of buildings is, of course, a natural means of utilizing this heat, but the great diversity in the rate of use of the two commodities renders impossible even an approximately complete realization of the theoretical economy.

The possibility of establishing a better relation between the rates of use is rather slight. The rate of heat supply is largely fixed by unalterable climatic conditions. The use of electricity for lighting is also governed by natural elements. The demand for electricity for industrial use, which now constitutes a major fraction of the output of most central stations, is not governed by these factors and is the only kind of load whose characteristics could conceivably be adjusted to suit the requirements for exhaust heat, and even this could probably not be done to any practicable extent.

Another important obstacle to the full use of this by-product heat through the warming of buildings is due to the great development of the central electric stations which in many industrial centres in the United States have so increased in size that the amount of exhaust heat which would be available as a by-product

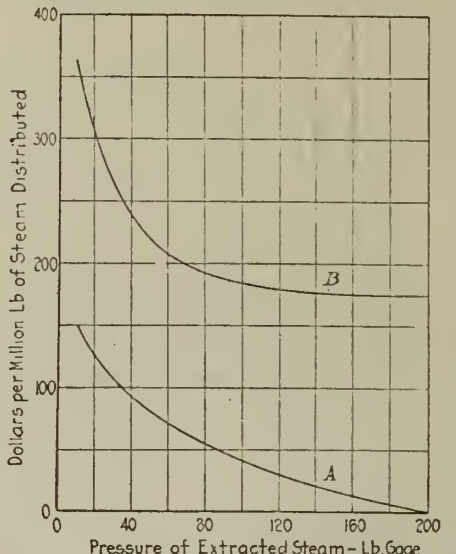

FIG. 1—CURVES SHOWING CREDIT (A) AND DEBIT (B) TO BLEEDER TURBINE PLANT FOR VARIOUS EXTRACTED STEAM PRESSURES.

is greatly in excess of that which it would be commercially feasible to distribute for the heating of buildings.

Systems of Central Heating

Assuming that a central heating load exists and is to be supplied by the electric company, there are in general three methods by which this can be done:

(a) The heating load can be served from a condensing generating station so designed that steam is available for heating at pressures above atmospheric after partial expansion in the electric generating units, the remainder of the steam used for current generation being fully expanded and condensed at high vacuum.

(b) Separate heating plants may be built in locations near the heating load and equipped with non-condensing generating units which will generate current only to the extent of the requirements for exhaust steam for heating, the remainder of the electricity being produced in a condensing station.

(c) The heating system may be supplied entirely with live steam from boiler plants located near the centre of the heating load.

It may so happen that the natural location for the main generation station serving a city is near the heating load, and if this is the case, the first method is preferable. In such a plant the use of bleeder turbines, designed so that steam can be extracted from the intermediate stages after partial expansion, offers great advantages. This arrangement has been successfully carried out in some instances and is probably the nearest possible approach to ideal conditions, since the duplication of equipment is reduced to a minimum.

Often, however, a consideration of land values or of railroad connections requires that the main condensing station be located at such a distance from the heating load as to preclude the possibility of transmitting steam from it. The Delray plant and the Connors Creek plant, the two main generating stations operated by The Detroit Edison Company, are respectively 3½ and 4½ miles from the heating district. A condensing plant, located on high-priced land near the heating district and with inconvenient railroad connections, or none, would be necessary if this first method were to be used. To such a plant, built for electricity supply and consequently, for reasons previously stated, burning more coal than a plant built solely for heating, this matter of proper railroad facilities is particularly important. Here again enters the matter of the transmission of steam, for seldom could the bleeder-turbine plant be located as favorably with reference to the heating load as could live steam plants, and the additional investment in transmission lines must therefore be charged against this plan.

The size of the pipes required to transmit a given quantity of steam over a given distance decreases as the density of the steam and the amount of pressure drop along the pipe increase. The most economical method from the standpoint of investment costs would be to extract steam from the high-pressure stages of the turbine; but the amount of electricity which could be generated per pound of steam would then be reduced. The relative values of these factors for an assumed river-front bleeder-turbine plant in Detroit are illustrated by the curves in Fig. 1. Curve A shows the total credit for the saving in coal and boiler capacity which could be allowed such a bleeder-turbine plant located on the river front and serving the existing Detroit heating system. Curve B shows the total

of the additional investment charges due to the higher-priced land on which the plant would be built, plus the investment charges and line losses involved in transmitting the steam from this river-front plant to the centres of the heating load. Even at higher extraction pressures the bleeder plant would not be justified under Detroit conditions because of its unfavorable location with respect to the heating load.

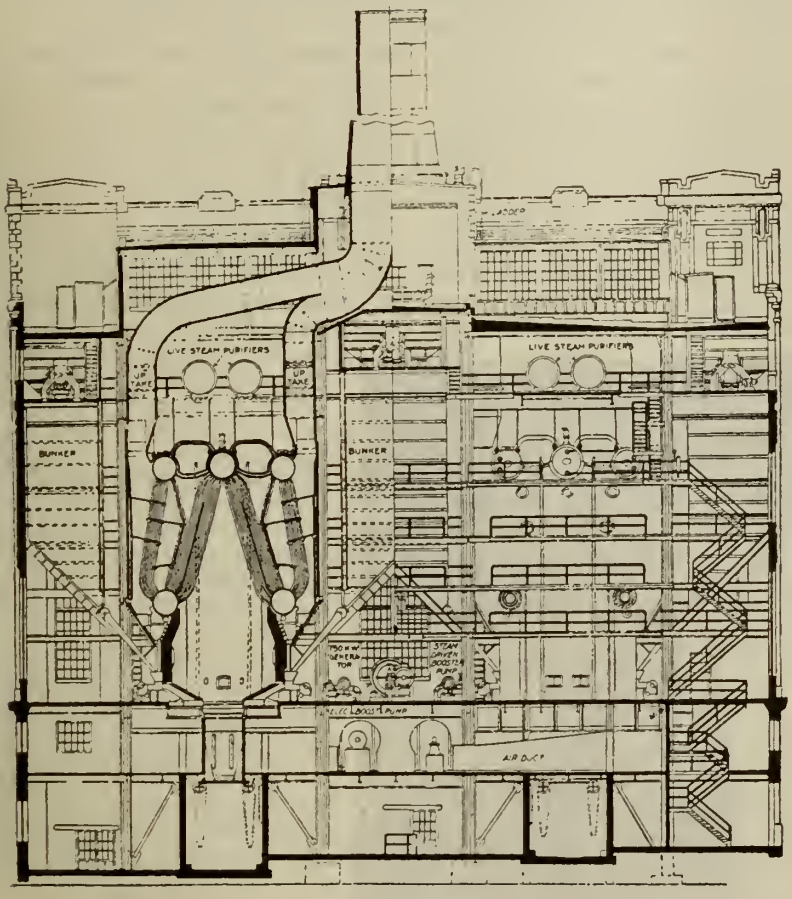

FIG. 2—CROSS-SECTION OF THE CONGRESS STREET PLANT.

The second plan above mentioned, namely, the building of plants located near the heating load and generating current only to the extent of the exhaust-steam requirements, involves somewhat different factors. In this case the capacity of the generating units will be determined by the heating requirements and the electricity generated by them will be the by-product. An essential requirement for the success of this plan is that the relation of these generating units to the electrical system as a whole be such as to allow their loads to be adjusted without restriction according to the momentary requirements for exhaust steam.

The value of such current as the heating plant will produce will be determined largely by the cost of producing an equal amount in the condensing stations. If the condensing stations do not produce current at an extremely low cost and, if other conditions are not unfavorable, this plan may prove very attractive and is in fact the mostly widely used method of combining the electrical and steam-heating plant. But unfavorable conditions surrounding the production of this relatively small amount of current may render its cost unattractive. The size of such generating units as might be installed in the heating plant may be so insignificant compared to the large size of the units in the condensing plant that the investment in the main station is not measurably reduced and the smaller units are therefore additional investment. The investment in steam-distribution mains is also much greater than when steam at higher pressures is used.

Development of Central Heating in Detroit

The immediate motive which, in 1903, led to the establishment of the central heating industry in Detroit was the possibility of obtaining a high thermal efficiency in the generation of electricity through the utilization of the exhaust steam. The generating plant from which steam was first supplied for heating had previously discharged its exhaust to the atmosphere. Owing to the building, at this time, by the Detroit Edison Company, of a large condensing plant, the smaller plant, with several others, would have been shut down, but the possibility of selling the exhaust steam made it appear desirable to continue the generation of current there to the extent of the exhaust steam requirements. Also, since the plant was located in a district served with direct current, the loss involved in converting an equivalent amount of alternating current received from the main plant to direct current would be saved for such current as might be generated there. The plant was in a high-class residence district and the heating service proved very popular, but the actual overall economy of the plant was not as great as had been anticipated.

A year later the construction of a central heating plant was begun in the business district of the city. This second project was undertaken, not as a means of disposing of exhaust steam, but for the express purpose of supplying the demand for central heating service among the owners of downtown buildings, who were considering shutting down their plants and purchasing electric service. The downtown plant was built primarily as a heating plant, and though provision was made for electric generating units they were never installed and the heating mains were supplied with steam from the boilers through reducing valves.

With the development of the large condensing generating stations the generation of current in the heating plants grew less and less attractive and when a third heating plant became necessary, because of increasing demand for steam heat, no provision was made for electric generators. The same practice was followed when, in 1916, the original exhaust-steam plant was rebuilt; and when the steam-distribution system of another company which had been engaged in the generation of electricity and the distribution of exhaust steam in the business district was purchased by the Detroit Edison Company, the new plant which was built to supply this district was also designed as a heating plant only. The entire combined distribution system is now being supplied with live steam from the boilers through reducing valves.

Since there are no generating units exhausting into the heating system the pressure carried on it is not limited by considerations of back pressure. On those sections of the system formerly supplied with exhaust steam at from 2 to 5 lb. pressure, the pressure now maintained ranges from 5 to 15 lb. and is being increased from year to year, toward the upper limit permitted by the strength

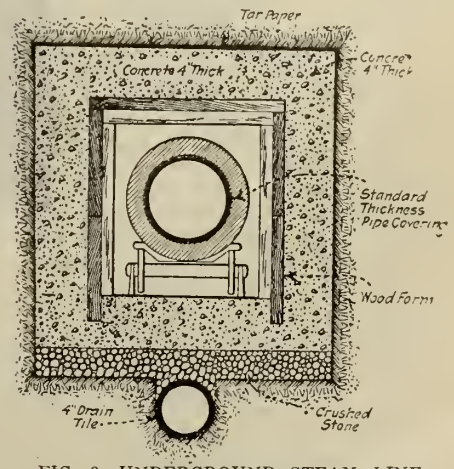

FIG. 3—UNDERGROUND STEAM LINE CONSTRUCTION.

of the pipes. The pressure on the section originally designed as a live-steam system is about 30 lb. Because of the increased capacity of the distribution system at higher pressures, due to the greater density of the steam and the greater allowable pressure drop, these higher distribution pressures are desirable.

The steam is delivered to the network of mains through connections made at the plants and also through feeders, from the plants which deliver steam to certain feeding points in the distribution network, the method being similar to the feeder and main method employed in electric-distribution systems.

Reasons For Using Live Steam

The supplying of live steam to the heating system and the abandonment of the generation of current in the heating plants is commercially justifiable, even though such current would be generated at a high thermal efficiency. The underlying reason for this is that there exist certain unfavorable conditions which outweigh the thermal advantage and make the total cost of such current higher than the generating cost at the large and efficient main generating stations.

The method of live-steam operation was adopted in Detroit before the recent great advance in the price of coal. The present high price of coal makes exhaust-steam operation appear somewhat more favorable and it is, of course, conceivable that at some future date a very high coal price may compel a change of policy. But with the cost of underground lines also increasing, the saving in distribution investment will probably continue to be sufficient to justify a continuation of the present methods.

Distribution System

The popularity of the heating service in Detroit has led to its development on an extensive scale. The present distribution system covers an area about 2 miles long and half a mile wide which includes the entire central shopping, business, and financial districts and a small portion of the residence district. About 2,700,000 sq. ft. of radiation, besides numerous water heaters and cooking fixtures, are served. The distribution system contains about 20 miles of tunnels. The four boiler plants which supply steam to the system contain 17,470 rated boiler horsepower, and they delivered in 1918 nearly two billion pounds of steam to the system. Over 1,700 consumers are served.

Though originally built in three distinct sections, the system is now a practically continuous network, and the plants are so much interconnected that the load can readily be shifted from one to another. In the spring and early autumn two of the four plants were the entire area.

The four boiler plants in Detroit which supply steam to the heating system are equipped with water-tube boilers and underfeed stokers and are of modern design throughout. Their location in the central district of the city necessarily restricts the amount of land which they may occupy and demands a suitable type of architecture, absolutely smokeless operation, and extreme cleanliness in the handling of coal and ashes.

A cross-section of the Congress street plant, the newest of the four, is shown in Fig. 2. It is designed to eventually contain four 1,300-h.p. boilers and two 2,600-h.p. boilers of the "W" type. In the effort to reduce the amount of attendance labor at this plant the auxiliaries are located, for the most part, on the boiler-room floor so as to be within convenient reach of the few men constituting the operating crew. Coal is hauled from bunkers at the railroad sidings to the plant in drop-bottom buckets of 5 tons capacity, which are lifted by a crane and emptied into overhead hoppers from which the coal is distributed by belt conveyers to the boiler bunkers. Ash-handling equipment is practically nil, the boilers being set at a sufficient elevation to allow wagons to be driven beneath the hoppers.

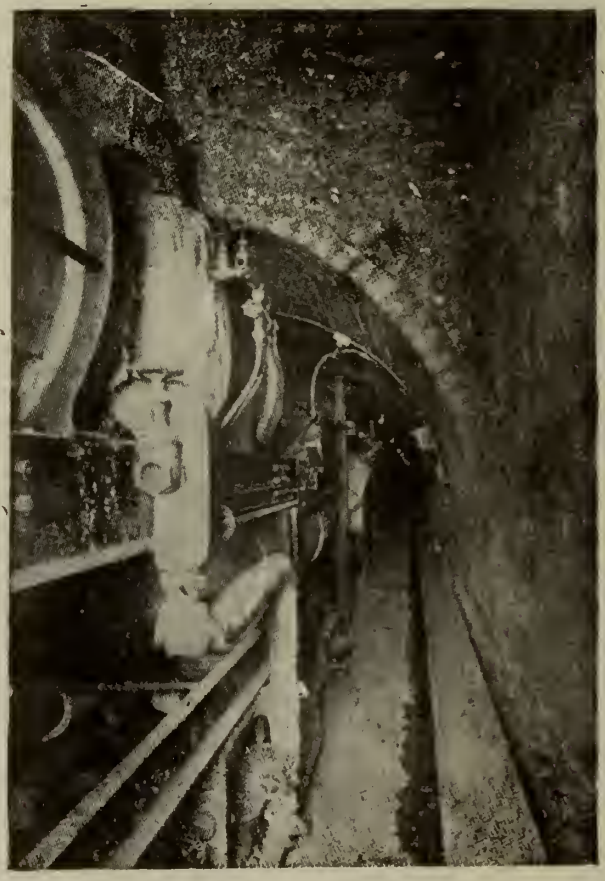

FIG. 4—TUNNEL CONSTRUCTION FOR STEAM LINES.

Because of the fact that only a relatively small amount of condensation is returned to the plants, careful treatment of the raw water is necessary. The feedwater flows through live-steam purifiers, operating at boiler pressure, in which the scale-forming materials are precipitated. In addition, sodium carbonate is fed in automatically graduated amounts to reduce the slight amount of hard scale-forming material which finds its way into the boiler. Although Detroit water is not a bad boiler water, these precautions are necessary because of the large percentage of make-up water and the rather high rates of steaming at which the boilers are sometimes driven.

The auxiliaries are almost entirely motor driven. The current is supplied by a 750-kw. turbo-generator unit exhausting into an open feedwater heater. The load carried on this generator is adjusted according to the requirements for exhaust steam for heating the feedwater and any excess current generated is delivered to the outside electric-distribution system. Conversely, if the electricity requirements of the plant exceed the output of the generator, current is drawn from the outside supply. Exhaust steam is thus made available for heating the feedwater and the advantages of motor-driven auxiliaries are also secured. Moreover the turbo-generator constittues a source of electricity supply for the plant in case of local interruption of the outside service.

Steam is generated at a pressure of 130 lb. gauge. This pressure is chosen in order to provide for considerable pressure drops in the outgoing feeders as calculated for present conditions. It may be raised to 160 lb. at some future date. The outgoing steam lines leave the plant through a tunnel shaft.

Feeders

Because of the great increase in connected load the transmission capacity of the distribution network, most of which was installed several years ago, is now quite inadequate. To have raised the pressure throughout the system would have increased its capacity; but the system pressure was permanently limited by the fact that most of the underground fittings are of a low-pressure pattern, and temporarily by the fact that in those sections of the system formerly supplied with exhaust steam the customers' installations are not provided with reducing valves Instead of attempting to change these conditions, which would have involved the reconstruction of much of the distribution network, the less expensive plan was adopted of running feeders from the plants to various centres of distribution. In selecting the pipe sizes for feeders, advantage is taken of the difference between boiler pressure and distribution pressure, and the size of the pipe is so chosen that at times of maximum load much or even all of this pressure drop will take place in the pipe itself. The diameter and the cost of the pipe line are thus materially reduced. In operation, the pressure of the steam de-

livered to the feeder is raised or lowered as required by the adjustment of a reducing valve at the plant, in order to maintain a constant pressure at the centre of distribution which the feeder supplies. The pressure existing at this centre of distribution is recorded at the plant by a long-distance gauge, electrically operated.

The velocity of the steam flow in the feeders at times of heavy load is very high. Velocities as great as 75,000 ft. per min. have been measured. This high velocity does not appear to be at all objectionable, however, there being no apparent erosion of the pipe and no hammer, or objectionable vibration. The fact that the steam is in a superheated state because of the pressure drop is an advantage in these respects. Feeders are constructed with long radius bends and where the connection is made to the distribution mains the diameter of the pipe is gradually increased by special taper fittings so as to reconvert a portion of the velocity head to static pressure.

A considerable pressure gradient is also allowed to take place in the distribution mains as well as in the feeders; but this is relatively small, since the upper limit is fixed by the allowable working pressure of the older mains. The more recently laid mains are capable of withstanding a working pressure of 125 lb. and the gradient in the mains can therefore be increased at some future date. From a standpoint of safety, however, the desirability of carrying pressures in excess of about 50 lb. on the service connections to buildings is questionable until further development in pressure-reducing apparatus is made.

This method of steam distribution is obviously an adaptation to previously existing conditions and would doubtless be modified if an entirely new system were being laid out.

Underground Construction

The distribution mains range in size from 20 in. near the stations to 4 in. at the outskirts of the system. The original underground pipes were laid in a segimental wood casing bound with wire. This construction has been fairly successful under favorable soil conditions, but the concrete conduit shown in Fig. 3 has been found to be superior in many respects and has been used exclusively for several years in all new construction. In this construction the pipe is insulated with a standard thickness of pipe covering and surrounded with an envelope of concrete poured over a wooden form, leaving an air space around the pipe. Proper underdrainage is of course essential.

The longitudinal expansion and contraction of the pipe, due to changes in its temperature, are absorbed, in the earlier construction, by means of expansion fittings of the copper-diaphragm type. In recent construction a slip joint, consisting of a brass sleeve, sliding in a packed gland, has been used. The use of slip joints decreases somewhat the cost of the pipe line as they will absorb more travel and can be placed at wider intervals than the diaphragm fitting.

The underground mains have not been laid sufficiently long to permit of an accurate estimate of their life. The oldest lines laid in wood casing have now been in service 15 years and, while the casing in many places has deteriorated considerably, in other places it is in fairly good condition. The concrete construction, dating back 10 years, seems to have deteriorated very little. The only repairs or replacements which have been made to date have been made necessary by external corrosion or pipe arising from some outside and local cause such as a water-pipe leak. An average life of 20 years for the wood log construction and 30 years for the concrete construction would seem to be a very conservative estimate. Soil conditions in that part of the city where the heating mains are laid are particularly favorable, the soil being very well drained. Manholes are located at intervals of about one city block (300 to 400 ft.), to house the slip joints, valves and bleeder traps.

In the heart of the business district the pipes are in tunnels, of which there are about 2 miles, lying from 25 to 40 ft. below the street level. In cross-section they are similar to a horseshoe and are built of brick, with concrete floors. (Fig. 4). For the most part they are about 6 ft. in heiht and 6 ft. wide. The tunnels are ventilated by suction fans which draw a small amount of air through them continuously and much larger amounts when it becomes necessary for men to work in them. Their temperature ranges between 90 and 130 deg. Fahr. When two or more pipes are to be laid under a street in a congested district it has proved desirable to build a tunnel to avoid the inconvenience to the public attendant upon tearing up the street, either for the original construction work or for subsequent changes. The tunnel permits of ready access to the pipes at any time, and since it is far below any other structures, no obstructions are met with. Tunnel construction is exceptionally simple in Detroit where the subsoil is a blue clay nearly impervious to water and well adapted to tunneling operations. The cost of tunnel construction is high, but the advantages gained are compensatory.

Distribution Losses

Distribution losses from various sources are considerable. Heat losses from the mains are the principal item. This loss can be controlled within limits in designing the system of the application of the proper amount of insulation, so as to produce the most economical relation between heat loss and investment costs. Besides the condensation losses in the mains and service connections, there are losses due to the leakage of steam from consumers' piping and air valves, and loss due to the escape of unmetered condensation, and the slip of meters. About 80 per cent. of the steam delivered by the plants is metered as condensation in the consumers' buildings. This figure compares favorably, considering the nature of the business, with the efficiency of electrical distribution. In 1918, for example, the ratio between the electrical plant output and the consumers' meter readings for the Detroit district was 83 per cent., the large items of loss being transmission, transformation and conversion.

The condensation from the buildings heated is returned to the plants only to

FIG. 5—CONDENSATION METER AND PRINCIPLE OF OPERATION.

a very limited extent. In the tunnels it is necessary to install a return line to receive the discharge from the traps on the steam lines, and wherever possible the condensation is drained from the adjacent buildings to this line. It is difficult and costly, however, in many cases, to arrange a gravity discharge from the building basements to the tunnel, and the cost of installing and operating pumps to handle the condensation would more than offset the value of the heat and the feedwater which would be salvaged.

In the districts not served from tunnels, all of the condensation is wasted to the sewers. Even with the present high cost of coal, return lines would scarcely be a profitable investment. Furthermore, they are short-lived, and any leakage from them is disastrous to adjacent steam lines. The proper method of salvaging the heat in the condensation is by means of an economizing coil in the consumer's building.

Consumer's Installations

The consumer's equipment includes, besides the usual radiators and piping, a pressure-reducing valve, which reduces the service pressure to the lower pressure required for heating, and a trap whose function is to discharge the water of condensation from the system.

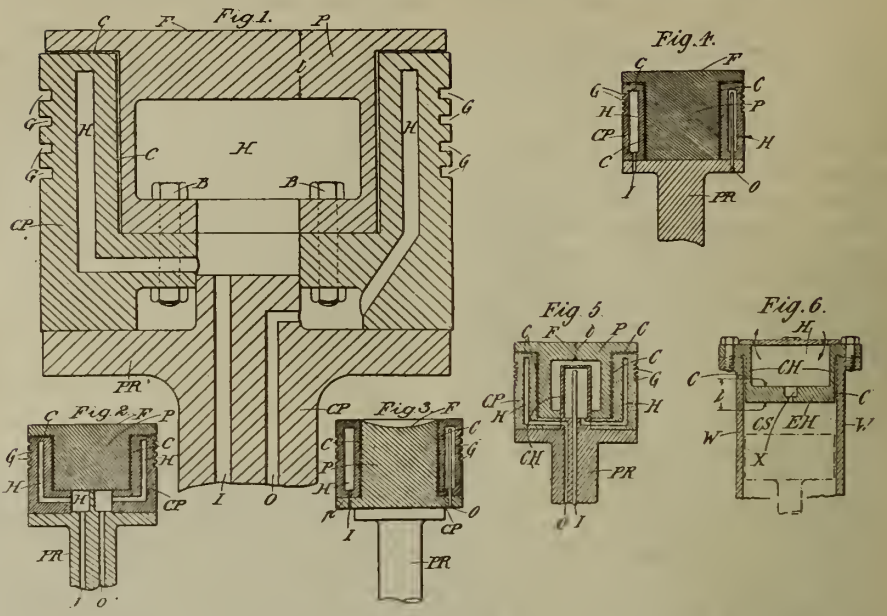
Economizing coils, utilizing the heat in the condensation, are recommended by the company, but not required. They are seldom installed in any but the largest buildings, as few consumers care to make the necessary investment even though a demonstrated saving can be made. In some buildings the condensation is passed through a surface heater which preheats the water used for lavatory purposes, and this seems to be the most satisfactory form of economizer for large buildings.

The regular heating season covers 8 months of the year, though summer service for cooking and water heating is supplied to a few consumers conveniently located. Cool weather in September usually makes necessary the commencement of service before the contract date of October 1. It has, in fact, been started in August. Steam was originally sold to some extent for power purposes, but this service is now practically discontinued.

Meters

The meter first used in Detroit was of the tilting type, consisting of a rectangular pan of two compartments hung on knife-edge or ball bearings, the compartments filling alternately and, when full, tipping the pan so as to bring the opposite compartment to the filling position. In 1907 a revolving meter was devised, consisting of a drum of four compartments which filled and dumped successively, the drum being revolved by the weight of the water. This meter was fairly successful and a few of that design are still in use, but a greatly improved design of revolving meter, operating on the same general principle (Fig. 5), was originated in 1909 by Hans Resert and is being used at present, with slight modifications.

THE DOXFORD DIESEL ENGINE



FIGS. 1-5—DIESEL ENGINE PISTON WITH PLUG MAINTAINING TEMPERATURE OF 800° F. FIG. 6—CYLINDER HEAD DESIGNED FOR SAME PURPOSE.

IN the ordinary Diesel engine the temperature to which it is necessary to raise the air within the cylinder at the end of the compression stroke necessitates a high degree of compression, which is generally about 480 lb. to 500 lb. per square inch. If it is possible to maintain some portion of the surfaces of the combustion chamber at a high temperature throughout the whole cycle, say at a temperature of not less than 800 degrees Fahrenheit, then it would be permissible to employ a much lower compression pressure, which could be in the neighborhood of 320 lb. per square inch.

The advantages derived from such an arrangement are obvious; in the first place it allows of a lighter design of engine owing to the reduced pressures, whilst it also facilitates the adoption of a system of solid injection of fuel, which does not present so many difficulties when the pressure to be overcome is not more than 320 lb. per square inch instead of the usual 480 or 500.

In a recent arrangement, patented by Mr. R. P. Doxford and Mr. K. O. Keller, this principle has been carried into effect. The design is intended to apply either to an ordinary vertical Diesel motor with a single piston and a normal cylinder head, or in an opposed-piston engine such as is being developed by Messrs. William Doxford and Sons, wherein two pistons moving outward and inward form on their inward stroke the combustion chamber between the surfaces of the two pistons and the cylinder walls around them.

Dealing with the patented design as it applies to this type of engine, and referring to Fig. 1, it will be noticed that there is a large plug (P), which is exposed at one end to the combustion chamber and to the hot gases, and is bolted at its inner end with the cylindrical portion (C P) of the piston, this being secured to the top end of the piston rod in any convenient manner. In the cylindrical portion of the piston rod are the usual grooves (G) for the piston rings, and in other respects there is no novelty in the design.

There is a large water space (H) for cooling both the cylindrical portion of the piston, the bolts holding the piston to the plug and the bottom of the plug, but the thickness of the plug "t" is sufficient to prevent the cooling water lowering the temperature of the plug at its outer face (F). There is a clearance (C) between the plug and the cylindrical portion of the piston, which allows expansion and contraction of the plug without causing any undesirable stresses in the piston. The plug should be preferably of mild steel, while the piston can be of cast-iron of suitable mixture. In an opposed-piston engine each piston would be designed in this way, whilst in the ordinary Diesel engine the cylinder cover would have a plug instead of the piston, the piston being of normal design. This is illustrated in Fig. 6, whilst Figs. 2, 3, 4, and 5 show alternative arrangements with the opposed-piston type of motor.

Apart from the advantages of lower compression pressure, as mentioned above, it is claimed that with this design, since the high temperature is maintained throughout the whole of the stroke, the efficacy of combustion does not fall off, which is liable to happen with the usual type, especially if solid injection is employed with heavy fuel oil. It is for this reason that with solid injection it is the custom to use the lighter grade of fuel oil.

We understand that this system is to be employed in the 3,000 h.p. four-cylinder motor of the opposed piston which is now being built by Messrs. Wm. Doxford and Sons, Ltd., at their Sunderland works for installation in a cargo ship.

Rules for Computing Required Radiation

"Domestic Engineering" Gives the Following Abstract of the Rules Submitted to the National District Heating Association by the Rules and Regulations' Committee

IT has been the desire of a great many members of the association for the past few years to have the National District Heating Association adopt a standard rule for figuring required steam and hot water radiation. There have been several papers on this subject presented before the association in the past and as there was such a great number of rules used by the various member companies, some of which did not check within 50 to 75 per cent. of each other, the adoption of a standard rule has been carried over from year to year by the association with no action taken.

Two years ago when the educational committee decided to get up an association handbook, it was suggested that they adopt a standard rule for figuring radiation, which would be known as the National District Heating Association rule, and make it a part of the handbook.

The Educational Committee was so busy that year with other matters that very little work was done on the radiation formula, and when the new committee on rules and regulations was appointed last year, the formulating of a standard rule for figuring radiation was turned over to them.

There have been numerous drafts of a proposed rule submitted to the committee members in the past three months, and as there are fourteen members on the committee, there has been a great deal of criticism and discussion on same, which resulted in a great many changes and additions to the original draft. Some of the members were of the opinion that the scientific method was too complicated, and that we should adopt a rule similar to rules Nos. 2 and 3. Other members were of the opinion that further additions should be made to the rule. As a result the rules which the committee is now submitting to the association for its approval and adoption do not meet with the individual ideas of each member, but the committee is agreed as a whole that if the proposed rules are adopted by the association as their standard, there is sufficient data in same so that the various members of the association can compile simplified formulas to fit their local conditions if they do not care to adopt rule No. 1 for general use.

Table No. 4 of rule No. 1, which gives the coefficients of heat transmission from the various types of radiation and pipe coils, is the latest addition to the proposed rules, and while they will probably not be used for general use, they are included for use by engineers who wish to go into complete detail in the design of heating systems.

Suggested rules Nos. 2 and 3 are samples of simplified rules which can be computed from the data in rule No. 1 to fit and fixed local conditions. It is the desire of the members of the Rules and Regulations Committee in publishing the proposed rules in the bulletin to have all members of the Rules and Regulations Committee in before the convention in June, at which time the formal adoption will be requested.

Rules for Determining Square Feet of Radiation Required to Heat a Building

The following rule No. 1 is what is known as the B.t.u. rule for figuring radiation and can be applied to any condition of temperature differences or any type of heating system, either steam or hot water. It is recommended for use to member companies, heating engineers, architects and heating contractors.

Rules Nos. 2 and 3 are examples of rules which are known as simplified or short-cut methods for computing required radiation. They are made up from the factors in rule No. 1 and fit a certain type of building construction and temperature difference. When circumstances make it advisable, in the case of any particular heating company, to have in use a simplified formula, a rule similar to rules Nos. 2 and 3 can be made up from the factors in rule No. 1 to fit local conditions, with an average type of building construction.

Any room or space having an opening which may communicate with the rooms or space to be heated, whether radiation be installed or not in such rooms or space must be considered in the measurements for space heated in either of the following ways, depending on the existing conditions:

1. If the unheated space is an active room and has a door or other opening which opens into the adjoining heated space and such doors or openings are left open the majority of the time, the entire space should be included in the measurements and sufficient radiation installed in the heated rooms.

2. If the unheated space is an active room and the doors or other openings are left open the majority of the time, the space and exposures of the unheated room should not be included in the measurements, but the walls adjoining the unheated and heated space should be taken as exposed surface in the measurements for the heated room. Basements and attics, which are used for storage purposes only, should not be considered as space to be heated.

Following are the three rules referred to above.

Rule No. 1

Since the radiation in any room must emit sufficient heat to compensate for all heat losses from that room and since heat is transmitted by different building materials at different rates, it follows that:

Radiation required = B.t.u. lost per hr. from room ÷ B.t.u. emitted per sq. ft. of radiation per hr. = H ÷ B.t.u. per hr. from radiation.

R = H ÷ X (temperature difference between contents of radiator and room temperature).

The value of X in the following computations is taken as 1.7 B.t.u., which is the coefficient of heat transmission from the type of radiation most generally used. See table No. 4 for coefficients for various types of radiation and pipe coils.

Gravity straight steam systems having from 1 to 3 lbs. pressure:

$$R = \frac{H}{1.7(220-70)} \text{ per season 3-lb. gauges} = \frac{H}{255}. \text{ Safe Value} = \frac{H}{250}$$

Vapor systems with individual traps on the return end of each radiation:

$$R = \frac{H}{1.7(212-70)} \text{ for steam at atmospheric pressure} = \frac{H}{241}$$

$$\text{Safe value} = \frac{240}{H}.$$

Atmospheric systems with open trap return and excess radiation for cooling surface:

$$R = \frac{H}{1.7\ (212-70) \div 120} = \frac{H}{200}$$

Hot water systems having an average of 170 degrees water:

$$R = \frac{H}{1.7(170-70) \quad 170} \qquad \frac{H}{165}$$

Theoretically, one B.t.u. will heat 55 cu. ft. of air one degree F., allowing for safety and simplicity in figuring. Fifty cu. ft. are used, which makes the constant for one change .02 B.t.u. per degree difference in temperature.

In computing required radiation for well-constructed residences and office buildings, good practice allows one change of air per hour; well-constructed store buildings two air changes per hour. For buildings of loose construction and those employing some method of forced ventilation, more air changes per hour will be considered, depending upon the existing conditions of buildings and ventilating system.

Table No. 1 shows the B.t.u. required to heat one cubic foot of space at various temperatures and air changes.

Table No. 2 shows the B.t.u. losses per hour through one square foot of various building materials with varying temperature differences.

Table No. 3 shows the percentage by

TABLE NO. 2.

	B.T.U. Difference K	Difference in Temperature Between Room and Outside. 50°	60°	70°	80°	85°	90°

Percentage of Increased Radiation Due to High Ceilings.

Room 12 to 14½ ft. from floor to ceiling	3%
Rooms 14½ to 18 ft. from floor to ceiling	6%
Rooms 18 ft. and above from floor to ceiling	10%

which the B.t.u. loss obtained from table No. 2 will be increased when the exposure is other than southern.

To compute the radiation required in any room:

First—Compute the B.t.u. required to heat the air in the room by multiplying the cubical contents by the proper factor.

Second—Compute the B. t. u. lost through the doors and windows by multiplying their area by the proper factor.

Third—Compute the B.t.u. lost through the walls, floor and ceilings in the same manner.

For steam radiation (one to three lbs. pressure)—Divide the sum of these results by 250 and the quotient is the number of square feet of straight steam radiation required.

For vapor radiation (with radiator traps)—Divide the sum of these results by 240 and the quotient is the number of square feet of vapor radiation required.

For atmospheric radiation (with extra cooling surface)—Divide the sum of these results by 200 and the quotient is the number of square feet of atmospheric radiation required.

For hot water radiation (water at 170 degrees F.)—Divide the sum of these results by 165 and the quotient is the number of square feet of hot water radiation required.

Percentage by which the heat losses given in table No. 2 are increased if the exposure is other than southern:

Rule No. 2

Rule No. 2 is to be used for computing the required steam radiation for a building assuming a temperature of 70 degrees inside with an outdoor temperature at zero, with 13-inch brick walls or average frame construction. Windows, single glass, set tight, and assuming one and one-half changes of air per hour in the building.

R=.008C+.08W+.35G.

R=Required steam radiation with system using steam at 1 to 3 lbs. pressure.

C=Cubic feet of space to be heated.

W=Square feet of exposed wall surface.

G=Square feet of exposed glass surface.

Note—No allowance made for extreme exposures.

Rule No. 3

Rule No. 3 can be used for computing required hot water radiation for a building, assuming a temperature of 70 degrees inside with an outdoor temperature at zero, with 13-inch brick walls or average frame construction. Windows, single glass, set tight, and assuming one and one-half changes of air per hour in the building.

R=.013C+.12W+.53G.

R=Required hot water radiation with average temperature of water in system of 170 degrees F.

C=Cubic feet of space to be heated.

W=Square feet of exposed wall surface.

G=Square feet of exposed glass surface.

Note—No allowance made for extreme exposures.

A simple device for improving the shearing strength of bolted joints in wooden structures has been brought out by Professor C. Forssell, of Stockholm. It takes the form of a corrugated washer, which is threaded on the bolt between the two pieces to be joined. The bolt is tightened against a pair of plain washers on the outside with sufficient pressure to force the corrugations into the wood. The strength of the joint is thus unaffected by the bolt hole, and depends on the friction between the two surfaces which are proportionate to the size of the washer and the depth of the corrugations. The strength of the joint is increased, according to Ingenioren, about twofold. The washers are known as "Bufo" washers, and made in various sizes, but all 1-16 in. thick, with corrugations about 9-32 in. high. In order to permit sinking into the wood, it is necessary to remove all knots at the joints to a depth of 3-16 inch. to 3-8 inch. The bolt is screwed up with spanners not less than 2 ft. to 2½ ft. long, and it is necessary to repeat the process after the first 48 hours and a further 72 hours.

An American still holds the world's airplane altitude record with 28,900 ft., as recent rereading of the British claimant's instruments showed a revised height of only 27,000 feet.

DIRECT USE OF COAL AS FUEL WASTES MANY VALUABLE BY-PRODUCTS

In a monograph on the subject of the "Coal Resources of Canada—Their Relation to the Industrial Development of the Country," by Mr. F. E. Lucas, published in The Final Report of the Fuel Controller, the advantages of using coal in the production of coke, rather than using coal directly as fuel, are pointed out. After showing the favorable qualities of coke as a fuel, the paper says:

"In the production of coke many valuable by-products are obtained; gas tar, ammonia, benzol, toluol, xylol, and naphtha, or combining the latter four, a motor fuel much superior to the best gasoline obtained.

"We are not getting anything like the amount of light, heat, or power we should, or could get, and in getting this extra light, heat, or power, we would not only be conserving the coal supply but geting cheaper power and at the same time recovering other products which would be of great economic value to the country and lead to the extension of existing industries and the establishment of new ones.

"Starting with the importation of anthracite, which is practically all used as domestic fuel. This can be almost entirely eliminated, and in so doing give as large returns on the invested capital as any industrial concern in the country.

"Referring back again to the by-products, a word now about their use and the markets available.

Gas

"If the plant is near a large city or thickly populated district, it might all be sold for domestic lighting and heating. This is done in many districts by selling direct to existing gas companies, for no gas company can produce gas at the price at which a by-product coke plant can afford to sell it. Or if there are large industrial works within reach, it can be sold to them and at such a price as to be more economical than coal, or it can be used in gas engines and power developed. The figure generally accepted as being reasonably conservative for gas-engine practice is 11,500 B. T. U. per horsepower, and it will readily be seen how tremendous quantities of power can be made available from this source.

Gas supplies for domestic use must have the sulphur extracted. This is done by iron oxide, from which the sulphur can be recovered for the manufacture of sulphuric acid, which is needed for the production of ammonium sulphate.

Tar

"This product can be used directly as a boiler or furnace steel by being burned in the same manner as oil, or it can very cheaply be dehydrated and the more highly volatile matter extracted and then used for road binding. Even for firing it would be found advantageous to dehydrate. Some tars, depending on the temperature and conditions of the coking process, can be used as fuel for Diesel engines. The most economical way to handle the tar, however, is to distill it and recover the various volatile fractions, such as the benzol, tuluol, naptha, the carbolic oils, creosote, naphthalene, and pitch.

"The benzol, toluol, naphtha, etc., can be added to that recovered directly from the gas, for motor fuel. The crude carbolic finds a market with manufacturers of antiseptics, colors, explosives, and a great deal is used in recent years on the manufactures of phonographic records, imitation amber for pipes, etc.

"So far as the value to the country is concerned, the creosote recovered is one of the most valuable by-products of the coal. Railway ties have doubled in price in the past ten years, and there is every prospect of a pro rata increase in further years. The forestry branch reports 19,-100,000 ties used on Canadian roads in one year. A fairly safe assumption would be a complete renewal of all ties every five years, while fifteen years might be taken as a reasonable average life for creosoted ties. The cost of creosoting is less than the cost of a new tie, so that the creosoting of the ties becomes not only a commercially attractive proposition, but will save many millions of feet of lumber annually.

"The same process of reasoning may be applied to mine ties and timbers, and also to bridge timbers.

"The general adoption of the creosoting proces would materially reduce this number in a few years. If we assume a consumption of only 10,000,000 ties per annum there would be required about 25,-000,000 gallons of creosote oil per year, or the distillation of 85,000,000 gallons of tar, which would in turn require the carbonizing of 8,000,000 tons of coal.

"The naphthalene finds a market as a color base. For the manufacture of deodorizers, disinfectants, moth balls, etc., and also in the manufacture of a chlorinated wax for use in electrical work.

Benzol

"Under this name is often included the tuluol, xylol and naphtha, which are recovered at the same time. Each of these products, together with naphthalene, can be recovered separately and refined to their chemically pure state, and there will undoubtedly be a market for a small quantity of each for solvents, dry cleaning, dyes, explosives, etc. During the war the toluol and a considerable portion of all benzol recovered was used in the manufacture of explosives.

"The greatest market now the war is over is undoubtedly to combine the four products, benzol, toluol, xylol and solvent naphtha, as a motor fuel, giving a product which distills between 78 and 165° C. This fuel has been carefully tested and found to give from 20 to 30 per cent. greater mileage than the best gasolene, with about 15 per cent. greater power, easier starting, no knock with advanced spark and actually less tendency for the formation of carbon in engine cylinders. Benzol itself comprises approximately 70 per cent of the fuel and this freezes at 44° F. The addition of the toluol and other products named, in the proportion in which they are recovered, brings the total fuel mixture down to a freezing point of approximately zero F., so that to make an all-year fuel for our climate we have to mix with sufficient gasolene to lower the freezing point still further. The addition of 25 to 30 per cent. of gasolene gives a freezing point low enough for most places, except in the north, where it might be necessary to add as high as 50 per cent.

"According to Government statistics, Canada's consumption of gasolene in 1916 was 74,000,000 gallons, of which 18,000,000 gallons was imported as distilled product, and most of the remainder was made from imported crude oils. So that it is evident that with a total Canadian production of say 20,000,000 tons of coal, if it was all carbonized and the motor fuel recovered, the market would still be far short of being satisfied. This does not take into consideration the fact of the continued yearly increase in consumption which is bound to occur.

"The pitch remaining can be made of almost any consistency desired. It can be made so hard that it can be pulverized and used as boiler fuel or in the same state that it can be used as a binder for briquettes. In its softer state it is also used as a binder for briquettes, for roofing and road making. It is also mixed with the lighter portion of the distillate for the manufacture of paint for special purposes.

Ammonia

"While this has been shown in the balance sheet as sulphate of ammonia which is used almost entirely as a fertilizer, yet it can be recovered in the form of concentrated liquor containing from 16 to 25 per cent. ammonia for the manufacture of explosives, or in the form of dry ammonia gas for refrigerator purposes, or as the aqua ammonia of commerce and chemistry. However, these are only small markets when compared with the market as a fertilizer. Its only competitor, as a nitrogenous fertilizer, is nitrate of soda from Chili, and as the population of the country increases and virgin lands become exhausted, we must, if we are to be fed, keep up the productiveness of the land in a great measure by the use of artificial fertilizers.

"An investigation into the yield per acre of Great Britain and the amount of nitrogenous fertilizer used when compared with America will readily substantiate these statements and set at rest any doubt regarding future markets. Considering the agricultural acreage of Canada and the fact that except for such parts as are growing leguminous crops the dressing for some crops should be even as high as 250 pounds of sulphate of ammonia per acre per year, we have further proof of the continuity of the market."

The Combustion Engineering Corporation, New York, has issued a bulletin on the C.E.C. tube scraping device. This bulletin describes a new and novel method of scraping the cinder and ash from the lower boiler tubes.

James Watt

THE one-hundreth anniversary of the death of James Watt, occurs at a time when the fruits of his genius have been fully manifest to the world. His discoveries and improvements in the use of steam marked the beginning of a new era in human progress, one in which the forces of nature were harnessed to do man's bidding and to work subservient to his will. For what his work stands for in human accomplishment as well as for the man himself the anniversary of his death, August 19th, is of more than passing interest to the engineer.

Suffering poor health and faced with many adverse circumstances, Watt found time and energy not only to engage in the inventive career which brought him fame, but also turned to philosophical pursuits and secured for himself the friendship of men of science and letters.

His contributions to engineering knowledge were much wider than those embraced in the science of steam engineering and included a machine for drawing in perspective, one for the automatic duplication of carved work of any kind, and in another line of endeavor an investigation into the composition of water, then unkown.

Artificial Respiration

THE use of artificial aids to respiration in the treatment of electric shock has been given much attention of late years by various engineering bodies. The Commission on Resuscitation from Electric Shock representing the American Medical Association, the National Electric Light Association and the American Institute of Electrical Engineers has recently issued a revised code of rules for this purpose. This set of rules reprinted in another part of this issue should be carefully read and memorized by all having to do with the operation of electrical equipment of any nature.

Better still it is strongly recommended by those having the safety and accident prevention features of plant operation at heart, that active instruction and training be given to those employees most likely to have use for resuscitation methods.

The value of the prone pressure method has been amply demonstrated in the past few years and it has rapidly supplanted older methods. It is also preferred by many to the use of mechanical respiration apparatus.

Aside from its use in the treatment of electrical shock it is also the best method for the resuscitation of those overcome by drowning, inhalation of gas, smoke or fumes, etc.

Familiarity Breeds Contempt--of Waste

IN an analysis of 100 colliery steam plants recently made in Great Britain a woeful state of affairs was found to exist. The average net efficiency of the boiler plants was only about 55.5 per cent., and that by carrying out a reorganization of these plants on modern lines it was estimated that a 70 per cent. efficiency could be easily obtained. This would correspond to a saving of about 3,900,000 tons of coal per annum and by burning refuse coal the total saving could be brought up to 6,600,000 tons for the same period.

Many of the boilers are of the old Lancashire type working in the open air and with chimney draught and hand firing, so with the conditions encountered the low efficiency is not to be wondered at. The same analysis also estimates the efficiency of the steam boiler plants for the whole of Great Britain was 60 per cent.

The above figures are worth while pondering over. While many of Canada's boiler rooms could hardly be as wasteful as the one hundred horrible examples cited above, yet in the majority of them 60 per cent. efficiency could be taken as a representative figure and one which could be improved upon in many cases.

Feed water is also treated of in this report and it is stated that, "Like all other industries, collieries have not realized the necessity of treating the feed water on correct lines in order to obtain fuel economy. . . . It would be very interesting to know how many thousands of pounds the colliery industry has lost in the way of damaged boilers from neglect of proper feed water treatment."

Most colliery steam plants are not fitted with economizers and have no means of utilizing the waste heat in the flue gases. Economizers installed on modern lines will reduce the coal bill, say 17.5 per cent. under average conditions.

Mr. A. M. Wickens is Bereaved

THE many friends in Canada and the United States of Mr. A. M. Wickens, to most of whom he is affectionately known as "Dad," will be grieved to hear of the death of Mrs. Wickens in her 81st year.

It is fifty-three years since the then Miss Taylor became the wife of Mr. Wickens, and it is a remarkable fact, that although there are three sons and three daughters, all of whom with the exception of one daughter, are married and have families, this is the first occasion that death has visited any of them. Mrs. Wickens was born in London, England, and lived for some years in Brantford, to which town she came from England at the age of seventeen years. For the past thirty-five years she has been a resident of Toronto.

"Dad" Wickens himself is probably the best known man in the stationary engineering life of this country. Born in Brantford 78 years ago, he has been connected with engineering ever since the beginning of his business career. The first firm he was connected with was that of Waterous, in his home town. He went from there to the United States and was employed for some years as a machinist, and during the Civil War was on some of the river gunboats which served in that memorable campaign. Returning to Canada he became connected with Warswick Guelph, making the Brown engine, and it was here his reputation as an engineer was made. He went from there to assume the responsibilities of chief engineer of the Toronto *Globe*, and was in charge there at the time they were burnt out, and during the rebuilding. This was one of the first plants in Toronto to generate their own electric current, and drive the presses by motor. His next position was that of Chief Mechanical Engineer to the Ontario Government, which position he resigned in 1903 to become Chief Engineer of the Canadian Casualty and Boiler Insurance Co., now the General Accident Assurance Co. of Canada. He was the first to hold this position, as the company had just been formed when he was appointed. He held this position until 1911, when he was appointed Special Excutive of the same company, and resigned a few months ago to become Assistant Plant Engineer of the Consolidated Rubber Company, with headquarters at Kitchener.

Mr. Wickens has been very active all his life in movements to elevate the position of the stationary engineer. In 1887 he was active in forming the Canadian Association of Stationary Engineers which has grown to be a factor of importance in engineering circles. He was also a member of the Technical School Board before that body was absorbed in the Board of Education. It is in a great measure due to his persistent interest and efforts that the graded certificate is to become an accomplished fact in Ontario.

Mr. Wickens is also a charter member of Canada Council 27 of the Universal Craftsmans' Council of Engineers.

Mrs. Wickens accompanied her husband to many of the conventions of the C.A.S.E., and was well known to many of the members. Members of the C.A.S.E., and POWER HOUSE readers all over Canada will join in the heartfelt sympathy we express here for the Grand Old Man in his sad bereavement.

The tendency in France at the present time is to favor the manufacture of internal combustion engines of the Diesel type, and of those types which resemble it in the use of heavy ores. Before the war the manufacture of these was a prosperous undertaking. Submarine engines of this type have been built in France weighing only 27 kg. per h.p., whereas the highest German engines weighed 50 kg. per h.p.

* * * *

Peat is found in Canada in deposits from a few acres to many square miles in area, and from a few feet to as much as 50 feet thick. Even when properly drained it contains from 85 per cent. to 90 per cent. of water, although this is not apparent from its appearance. There are great deposits in Ontario and Quebec, where other fuel is conspicuously scarce. Much money has been lost in the endeavor to convert it into a commercial fuel, and experiments are still being carried out. Investigation in the Alfred Bog, where the most extensive operations in Canada have taken place, show that the peat there weighs 66 lbs. per cubic foot and contains 87½ per cent. water and 12½ per cent. solids, even when properly drained. The solid material analyzes out as 68 per cent. volatile and combustible material, 24 to 26 per cent. fixed carbon, and 5 to 7 per cent. ash. In no case has the phosphorus content been found as more than 0.09 per cent., and it is on the average about 0.03 per cent. The nitrogen content varies between 1.13 and 2.7 per cent.

* * * *

The chief reasons which have militated against the successful use of peat fuel have been the failure to recognize the fact that, owing to the colloidal properties of peat, enough water cannot be pressed out of it; that there are not enough heat units in peat to drive off the surplus water and still leave enough heat for other purposes; that the combination of driving off water by pressure and by heat compares unfavorably in the fuel produced with that obtained by grinding the peat up in its wet state and drying it atmospherically, which is a much cheaper method of preparation; and finally, that artificially dried peat has to be briquetted before use, which is a very difficult operation.

* * * *

One ton of peat containing 50 per cent. or even 60 per cent. moisture, if the latest producer gas plants are used, contains about 20,000 cubic feet of high-grade illuminating gas with 160 B.t.u. per cubic foot, or 40,000 cubic feet of medium-grade heating and power gases, with 130 B.t.u. per cubic foot, or 80,000 cubic feet of low-grade heating and power gases at about 100 to 110 B.t.u. per cubic foot. This latter grade of gas is the most economical per heat unit for steel works. In addition to the above, there are also the following by-products to be obtained by retorting per ton of peat:—800 lbs. of coke, 100 lbs. of ammonium sulphate, 40 lbs. of crude oil, 16 lbs. of paraffin, 4 to 8 lbs. of pitch, and 5 lbs. of creosote, benzol, alcohol, toluol, and antiseptics.

* * * *

An electric-heating system which utilizes power that would otherwise go to waste has been installed in a school in a southern European city. The existing hot-water pipes and radiators are connected with a well-insulated water tank of 1,300-gal. capacity. In this reservoir electric resistances are built and at night are supplied with current which raises the water to well above the boiling point. The cost of the current is low because the water power used to produce it normally would go to waste. During the day the hot water is allowed to circulate through the radiators, its volume being sufficient to warm the rooms without using more current. The desired temperature is maintained by a thermostat.

* * * *

Next time you "light up" think of this: About 10,000 matches are scratched in this country every second that passes, and of these 95 per cent. are used by smokers to fire pipe, cigar, or cigarette.

The man whose head for figures turned out that information also estimates that the time lost by the smokers in lighting matches—not in smoking—is worth $513,024 each eight-hour working day. He arrives at his estimate by figuring that it takes fifteen seconds to scratch a match and use the light, and that 213,759 men, whose time is worth thirty cents an hour, are holding matches at the same time, thus losing golden minutes at the rate of $1,068 a minute, or $64,128 an hour.

No one, so far as we can learn, has figured out how large a percentage of the match-scratchers throw away the matches while they are still burning, but it has been estimated that half of the fires which cost the United States $250,000,000 a year are caused by carelessness.

Wood, phosphorus, chlorate of potash, rosin, whiting, and powdered flint are the makings of this little device.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

Readers are invited to send in answers to these problems, as they have been chosen for their interest and application to the practical side of power plant operation.

Perhaps you, too, have some pet problems, or hard nuts which you would like to ask your fellow engineers; if so, send them along for the benefit of others.

Answers, together with the original question, will be published in the issues following the appearance of the question.

Questions Before the House

64. Explain the difference between outside lap and inside lap of a D slide valve?

65. Explain the difference, if there is any, between piston clearance and clearance volume?

66. Is it possible to cut off with a D slide valve operated by an eccentric, having no outside lap and no lead?

67. Suppose you had a plain slide valve engine, and you wished to make the cut-off earlier, what would you do? The port opening is to be the same as before.

68. What is the effect of increasing the inside lap of a D slide valve?

69. How can the valve be given a greater travel than the throw of the eccentric?

70. How does the angularity of the connecting rod effect compression?

71. A 14 in. by 28 in. engine has a clearance volume of 247 cubic inches. Express the clearance in per cent.

72. In a 36 in. by 60 in. engine the steam is cut off when the piston has moved over 21 inches of its stroke. The clearance being 2 per cent.; find the real cut-off.

73. What is the ratio of expansion of the engine given in question 9?

74. A 44 in. by 80 in. engine is to run at 75 r.p.m. What actual diameter of steam and exhaust pipes should be used?

75. About what scale of spring is usually selected for a given boiler pressure?

76. What is the principal objection to the lazy-tongs and pantograph reducing motions?

77. What is meant by the vacuum line on an indicator diagram, and how is its position located?

78. In plain slide valve engine, how would you remedy too early admission, and what effect would this have on the other events of the stroke?

79. If one end of a cylinder with a slide valve is found to be doing more work than the other, how can the fault be remedied?

Questions Answered

Question.—47. What is the object of the safety valve?

Answer.—To prevent the steam pressure from rising above a fixed limit.

Question.—48. How should a safety valve be connected to a boiler?

Answer.—The safety valve should be connected directly to the boiler so that there is no possible chance of cutting off communication between the boiler and the safety valve.

Question.—49. How are safety valves, in practice, adjusted for a given steam pressure?

Answer.—Spring loaded safety valves are always adjusted by comparison with an accurate steam gauge, and this practice is now generally employed when setting the lever safety valve also.

Question.—50. What is the object of a gaugecock?

Answer.—A gaugecock is a simple cock or valve attached either directly to the boiler or, preferably, to a water column for the purpose of testing the water level in the boiler. Three gaugecocks are generally employed. The lowest is placed at the lowest level the water may safely attain, and the uppermost at the higher desirable level, the third is placed midway between the other two.

Question.—51. What is the purpose of water alarms and fusible plugs?

Answer.—A water alarm is a device attached to a boiler to give warning by blowing a whistle when the water in the boiler is either too low or too high. The fusible plug is another device which gives warning when the water is too low. It consists of a threaded brass plug filled with some alloy which has a low melting point, and if the water gets too low the plug is exposed to the hot gases and the alloy melts, thus allowing steam to escape and warning the attendant in charge.

Question.—52. What is the object of running boiler feed-pumps at a slow speed?

Answer.—As the boiler is constantly evaporating the water supplied to it, it is only necessary to replenish an amount equal to that evaporated. Therefore, feed pumps ought to be run as low as possible, thereby reducing the wear and tear on the valves.

Question.—53. What is combustion?

Answer.—Combustion is the chemical combination of oxygen with carbon or hydrogen, or both.

Question.—54. What is the principal element in the composition of all fuels?

Answer.—Carbon.

Question.—55. How many pounds of water at 212 deg. can be evaporated into steam at the same temperature by a pound of coal of the following composition: Carbon, 74 per cent.; hydrogen, 8 per cent.; oxygen, 5 per cent., and ash, 13 per cent.?

Answer.—The quantities of heat produced by the complete combustion of the elements composing the fuels have been found by experiment and are as follows:

	B.t.u. per lb.
Hydrogen	62,000
Carbon burned to CO_2	14,600
Carbon burned to CO	4,400

RULE.—To find the heat of combustion of one pound of fuel, multiply the percentage of carbon by 146 and the percentage of hydrogen by 620 and the products and the sum will be the required heat of combustion in B.t.u.

The heat of combustion, according to this rule of this fuel is $146 \times 74 + 620 \times 8 = 15{,}764$ B.t.u. The steam table shows that it takes 966 B.t.u. to change one pound of water at 212 deg. into steam at 212 deg., therefore

$$15{,}764 : 966 = 16.32 \text{ lbs.}$$

Question.—55. In what way will the presence of sulphur in steel affect the latter?

Answer.—A very small percentage of phosphorus or sulphur will render the metal useless.

Question.—56. What joint in a cylindrical boiler is subjected to the greater stress?

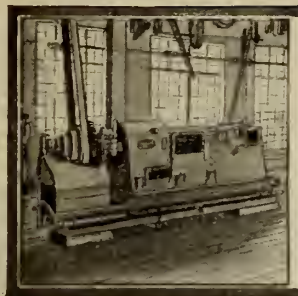
Answer.—The longitudinal joint.

Question.—57. What is the bursting pressure of a seamless steel tube 12 in. in diam., 3-16 in. thick, and having a tensile strength of 64,000 pounds per sq. in.?

Answer. — $64{,}000 \times 3\text{-}16 \times 2 : 12 =$ 2,000 lbs. per sq. in.

Question.—58. What is the working pressure allowable on a boiler shell 60 in. in diam. and 11-32 in. thick, if the material has a tensile strength of 60,000 lbs. per sq. in. and the longitudinal joints

(Continued on page 379)



NEW POWER PLANT EQUIPMENT

RENEWABLE FUSES

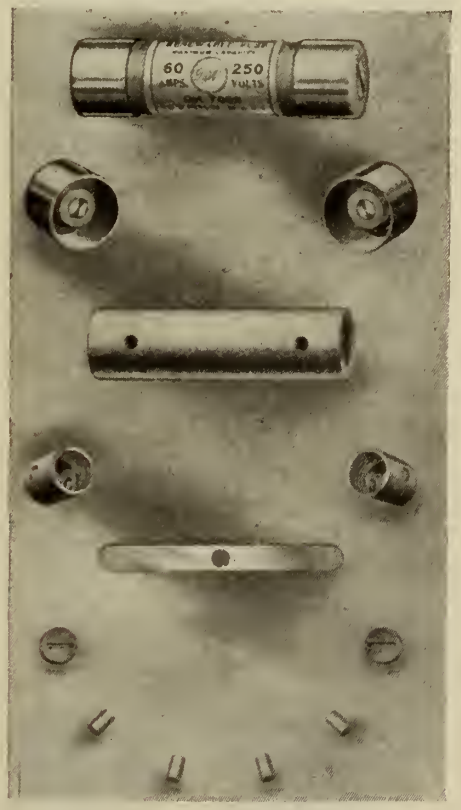
DURING the past few years a type of enclosed fuse in which the fusible element can be readily renewed has been favorably received by many buyers. It has appealed particularly to certain classes of industrials who employ numerous motors and whose consumption of fuses is large.

The renewable fuses that have heretofore been supplied to the trade have been so expensively designed that their use has been restricted to a limited field. The first cost of these fuses ranges between two to three times that of the standard type. Thus an actual saving could be effected only in plants where the percentage of blowouts per installation is very large. Moreover, the expense of carrying an increased fuse investment has considerably reduced this saving.

The object of the renewable fuse is to afford less expensive protection. It has, therefore, been the goal of the manufacturers in the design of the "D & W" renewable fuse to provide one which will enable the user to secure a maximum saving. Its introduction permits those who desire this type of fuse to obtain a saving from every standpoint, since it not only effects a saving in the first cost but also a reduced labor cost of reassembling, due to the ease of renewing the blown link. Furthermore, in event of the tube becoming scorched or weakened in long service, the tube only need be replaced, as the brass caps are removable.

The mechanical construction of the "D & W" renewable fuse is simple and effective. The ferrule type consists of a fibre tube having a steel sleeve held in each end by two pins. The inside of each sleeve is threaded to receive a metal plug, which is securely attached inside of the brass ferrule. The sleeve has a seat beyond the threaded portion, on which a slotted washer rests. The link is clamped between this metal washer and the end of the metal plug, both of which are held in position by the threaded sleeve. By this means permanent electrical contact between the link and terminal structure is insured. This eliminates the trouble experienced with that type of renewable fuse in which the pressure necessary to maintain link contact is transmitted through a part of the fibre tube. Shrinkage expansion or warping of the fibre so depended on results in a corresponding change in the pressure applied to the contacts. It is impossible to maintain a permanently good connection between the link and terminal with such a construction.

The steel parts of "D & W" renewable fuses are oxidized to prevent the molten or vaporized link metal from attaching itself to these parts. In some other types of reloadable fuses much difficulty is experienced in taking the fuse apart after it has blown on a great overload or short circuit because the fusible metal readily solders itself to the terminal parts of the fuse when these are made of brass. The construction embodying oxidized steel absolutely prevents this difficulty.



RENEWABLE FUSE.

In the design of the "D. and W." knife blade type renewable fuses, the makers, the D. and W. Fuse Co., Providence, R.I., have carried out the same idea as in the fuses of smaller capacity, that of making a fuse very easy to load and disassemble after the fuse has blown; and with extra heavy parts to withstand the great strain developed when the fuse blows.

A rugged type of fuse casing is most essential in the renewable type, for unless a fuse casing is strong enough to be refused over and over again the whole object of a renewable fuse is lost.

In these fuses the heavy fibre tubing is reinforced by permanently fastening inner cap to both ends of the tube. These caps are slotted to receive the fuse link and are designed to engage the blades and lock when in position when given a quarter turn. Asbestos lined metal washers are then slipped over the blades to align them properly, and to regulate the escape of gas. The outer caps are then screwed into place, engaging metal threads on the outside of the inner caps, completing the assembling of the fuse.

All parts subject to severe strain are made of steel, brass plated to prevent corrosion.

The makers have also developed a type of fusible element which they designate as their expulsion or jacketed fuse link.

This link consists of a flat strip of metal with the central portion slotted and closely wrapped with a covering of specially treated asbestos. The jacket is unaffected by the high temperatures in service, and remains intact even when the fuse blows on a short circuit. When the rupture occurs an arc is formed, converting the metal within the jacket into vapor, thereby developing internal pressure within the jacket. This causes a blast of hot gases in each direction from the centre of the fuse, tending to extinguish the arc. As the metal is burned back towards the terminals the jacket drops out, thus breaking up mechanically any strata of vaporized gas which might extend from one terminal of the burning link to the other, and thereby positively opening the circuit.

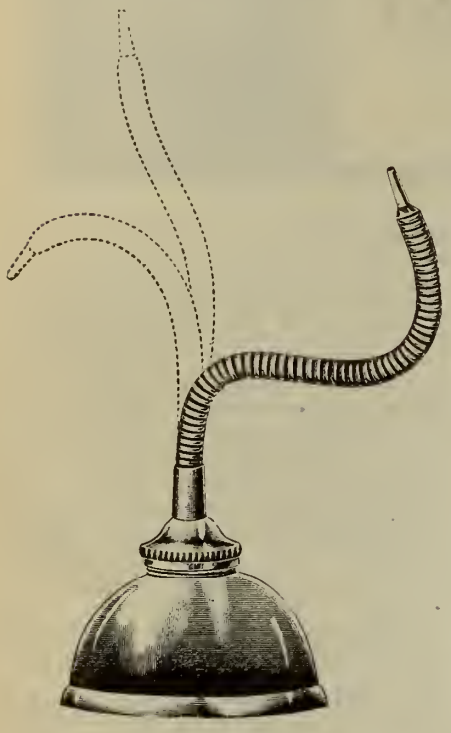
With this design is secured an effective expulsive action, tending to materially reduce the arc, particularly on moderate overloads, thereby securing a greater factor of safety and longer life of the casing. Another advantage of this link is its increased radiation surface, effected through the use of the jacket, which makes possible a considerable reduction in the total mass of metal required for a given current. By this means a material lowering of the pressures developed when the fuse blows on a dead short circuit is obtained.

ALL-WAY OILERS

The ordinary oil can with rigid spout is at best an awkward thing to handle and use in all positions. A new development recently placed on the market should find much use in the engine room

and other places where much oiling has to be done.

It is in brief an oiler fitted with a flexible steel spout, made to be bent in



ALL-WAY OILER.

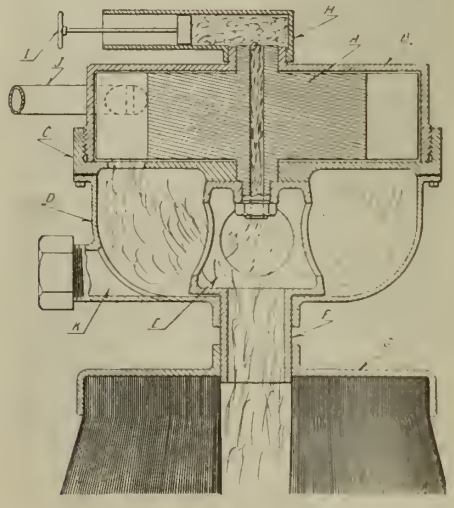
any desired angle or position without breaking or interfering with the flow of oil. There is no waste of oil when using this oiler, as no matter where oil hole or parts of machinery to be oiled are located, they can easily be reached without any trouble or waste of oil. The spout is simply bent to suit the position where oil is to be applied.

This oiler is fitted with a cleaning device at the end of the spout, and the same device also prevents oil from flowing too freely. The all-way oiler is strongly made of copper plated steel in different sizes and shapes by the All-way Oiler Manufacturing Co., Toronto, Ont.

SMALL LABORLESS WATER MOTOR

The washing of automobiles, railway coaches, boats, etc., is a task that often tries the patience of the operator handling the brush, as it is generally necessary to frequently apply the brush into the bucket that contains the washing material. The sketch herewith illustrates a convenient form of water motor, in conjunction with a cotton brush, that performs the washing operation with the minimum expenditure of effort on the part of the person using the appliance. The turbine wheel, A, that receives the force of the incoming water, is encased in the body, B, the lower cover, C, being screwed in place after the turbine has been placed in position. Secured to the face of the cover, C, is the exhaust chamber, D, into which the whirling water is discharged after expending its energy on the wheel. The central tubular shaft, E, is secured to the lower end of the turbine and extends through the bottom part of the casing, D. At the extreme end of the hollow shaft, F, the brush, G, is secured. On the upper end of the turbine casing is the small cylinder, H, in which is kept a supply of soap in chip or paste form. To the supply or feed pipe, J, is secured a handle suitable for the work in hand. This handle is hollow and split at the motor end to encircle the casing, and is pivoted at a bearing at either side. This arrangement permits the brush to be used at any angle.

The operation of the laborless water motor may be stated as follows: The water, steam or air, as the case may be, enters through the hollow handle and through the feed pipe, J, this latter being of rubber tubing to allow of free movement from one position to another. The water rushing against the blades of the turbine, A, causes the latter to revolve, the speed depending on the velocity of the incoming water. The water exhausts into the casing, D, in a swirling condition, and passes through the openings in the tubular shaft, E, and thence through the hollow shaft, F, to the cotton brush, G. To facilitate the washing operation, and where such is necessary, the soap cylinder is placed on the top of the turbine casing. By slight pressure on the handle, I, sufficient soap is pressed through the central opening in the turbine and mixes freely with the water passing to the brush. Provision is also made for drying operations by making connection at the opening, K,



WATER MOTOR WASHER.

located on the side. These laborless water motors have been designed by C. C. Howard, Toronto, Ont.

A WONDERFUL AND UNIQUE DRIVING CLUTCH

A difficulty which engineers have often experienced with regard to the electric driving of machinery and line shafting has been to start and accelerate a load or mass requiring a large starting torque without the use of special switchgear, and with a minimum starting current. For this reason many motor drives which otherwise could have been quite ideal have had to be abandoned for some alternative method, and drives which are actually in practice are proving very unsatisfactory and costly.

To overcome this difficulty, Messrs. Thomas Broadbent & Sons, Ltd., Huddersfield, have designed a centrifugal driving clutch which, for effectiveness and simplicity is quite unique. As this clutch is quite automatic it requires no further attention once it is fitted, and as there are little or no wearing parts it is practically impossible for it to get out of order. This device is particularly valuable where the electric supply authorities limit the starting current of motors to a low value, or where the machines are frequently stopped and started under load.

The function of this clutch is to enable the motor to start up unloaded, the load being gradually applied as the motor accelerates. The rate of acceleration can be predetermined when designing the clutch, and is entirely independent of the operator. The switchgear can be of the simplest form (in many cases the motor can be switched direct on to the mains without any starting resistances) and as the clutch can be designed to slip at any desired overload, other overload devices are unnecessary.

The load is applied to the motor gradually and the driven machine accelerates without jerk. As the clutch also acts as a flexible coupling it corrects slight errors in alignment and presents sudden loads or shocks being transmitted to the motor.

The clutch is eminently suitable for use with alternating-current motors of the squirrel-cage rotor type. As is well known, this is the simplest and cheapest type of motor, the only wearing parts being the bearings. Up to now, however, its poor starting torque, especially in the single-phase type, has prevented its use in many cases. This disadvantage is at once overcome by using a centrifugal clutch, and complimented switchgear with its troublesome coils, resistances, etc., is unnecessary. Belt-shifting arrangements are also done away with, and slipping and wear of belts avoided.

The clutch is quite noiseless in its action as it is perfectly balanced, has no loose parts to chatter, and is equally effective in either direction of rotation.

Many of the most prominent firms in England are now using these clutches which have proved themselves to be a great success both with regard to current consumption and cost of machinery.

Magnetized screwdrivers are useful for many classes of work, the carbon steel of which screwdrivers are made being capable of retaining considerable magnetism. A screwdriver which will retain a considerably stronger magnetism than an ordinary one, may be made from a round piece of tool steel, or preferably of tungsten steel, by simply grinding the end of a bar into the form of a very short screwdriver blade.

The Operators' Point of View

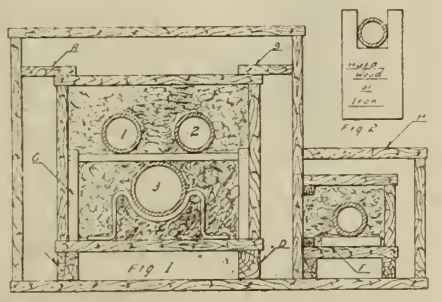
PROTECTING PIPES ABOVE GROUND

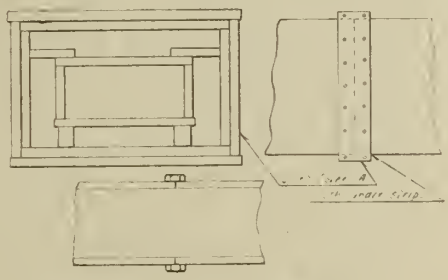
IN the section of the country where I am employed, the ground was principally stone, sometimes with only a foot or two or earth on top, often the stone comes right up to the surface.. It is a work of labor and expense to get below frost level, as much of the stone has to be drilled and blasted out. To get away from the very high cost of going below frost level, boxes such as are shown in Fig. 1 have been used with excellent results. The cost of such a box, both in labor and material, is considerable, but only a very small percentage of what the blasting process costs, for in the latter case, besides the cost of the blasting, there is the expense of carting away the stone and buying and carting earth to fill up the pipe trench, in any case, outside of the cold water pipe, the pipes have to be encased in some kind of a covering material, such as tile pipe, etc. So, even with the high cost of lumber, the ultimate cost of such boxes is not so great over the others.

I know of such boxes that have been in use for over ten years and are still in good condition.

With an outside temperature often going as low as 27 below zero, no freezings have occurred in such boxes with the tops only a few inches below the earth's surface. However, it is necessary to use considerable care in putting the boxes together, and in coating the joints and the surface of the outside box boards. In the sketch, 2, is the live steam main, 1 is the return main and 3 is a large hot water main. The inside box is held central by pieces nailed on at intervals along the box, as shown at A, B, C, D. The pipe roller support, G, is shown at Fig. 2 also; it can be made from hardwood or iron, and is fastened to the side of the box. The cold water pipe is shown in box H. The pipe can rest on pieces of wood laid several feet apart.

The inside of the small boxes are filled with dry asbestos, mineral wool, ground or broken mica, or even a light dry earth loam. Strips of cotton or other cloth are cut, soaked in an oil paint, and laid between the box joints when building them. The space between the boxes is left empty. Any knot or other hole in the boards should be covered with a piece of wood nailed on, as the efficiency of the boxes to keep out frost depends to a large extent on the tightness of the boxes . All the joints of the boards should have their edges planed smooth and straight before putting them together. The outside of the boxes, bottoms, sides and top, should receive a coating of tar, pitch or other wood preservative, otherwise the boxes will become wet after every rain and will soon rot away. I have found that pipes, 1 and 2, laid on pipe rollers,





RUNNING PIPES OVERGROUND.

and covered with some material, seldom, never in my own personal experience, move to the sides of the boxes if ample provision is made for expansion. However, it would be no difficult matter to instal some kind of a check to prevent this if desired. I may state that any water which may reach trenches here finds its way out through openings between the stone.

JAS. E. NOBLE.

MEANING OF POSITIVE POLARITY AND NEGATIVE POLARITY

By W. G. Hammond

(Copyright. All rights reserved)

The terms "positive polarity" and "negative polarity" are best defined on the basis of the concept of electric potential. An electric current always flows from a point of higher potential to a point of lower potential. On this basis the positive pole, Pd (Fig. 1) or terminal of an electrical-energy-delivering device, D, is the terminal from which the electric current flows from that device to the external circuit. The negative terminal of the device, Nd, is the one into which the current flows from the external circuit. It also follows that for any energy-receiving or energy-consuming device the positive terminal Pr is the one into which the current flows from the external circuit and the negative terminal, Nr, is the one from which the current flows to the external circuit.

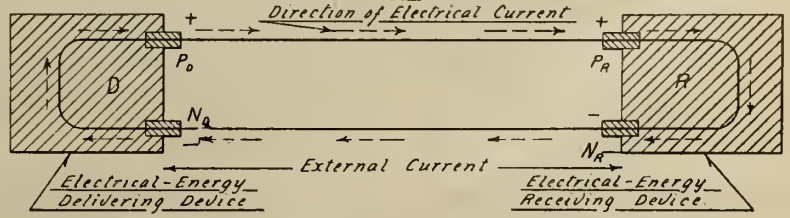
DRY CELLS DELIVER GREATER CURRENT WHEN WARM

By George W. Wesley

(Copyright. All rights reserved.)

It is an observed, but a not generally appreciated, fact that dry cells will deliver greater currents when warm than when cold. Hence it is neither wise or fair to dry battery manufacturers to test a dry cell from a lot which has just been received from transit in a cold freight car. Before cells which have been shipped in barrels in cold weather are tested, they should be allowed to remain in a moderately warm room for a period of from 24 to 48 hours, so that their temperatures may become approximately 70 degrees F. before the test is made. It requires a considerable time for the cells, which were at the centre of the barrel during shipment to attain the temperature of the surrounding air.

A cell which will, on short circuit, at a temperature of 30 degrees F., produce a current of 30 amp., will produce approximately the following currents at other degrees, 20 amp.; 60 degrees, 10 amp.; 40 degrees, 30 amp.; 60 degrees, 25 amp.; 100 degrees, 35 amp. The decrease in current output at the low temperature does not imply a permanent injury to the cell, because such a cell, when again raised to normal temperature, will de-



MEANING OF POSITIVE AND NEGATIVE POLARITY

liver its normal current output.

On the other hand, dry cells should not be stored in a hot place. The heat dries them out, and hence decreases prematurely their outputs. It is, therefore, the better practice to store the cells in cold rooms, but to permit them to remain in a reasonably warm room for a number of hours before they are used or are tested for current output.

SOME CEMENTS FOR PIPE JOINTS

By B. C. Bergman

(Copyright. All rights reserved.)

A cement which is very popular with operating engineers for making screw joints in pipes steam tight is made of graphite and cylinder oil. Just enough cylinder oil is mixed in with the powdered graphite to convert it into a thick paste.

A cement which is satisfactory for both water and steam pipes has this composition: 4 lb. whiting, 10 lb. fine yellow ochre, 4 lb. ground litharge and ½ lb. hemp cut into fine bits. These ingredients are mixed thoroughly with linseed oil to form a thick paste. The compound is applied on the threads of the pipe and on the threaded portions of the fittings into which the pipe screws.

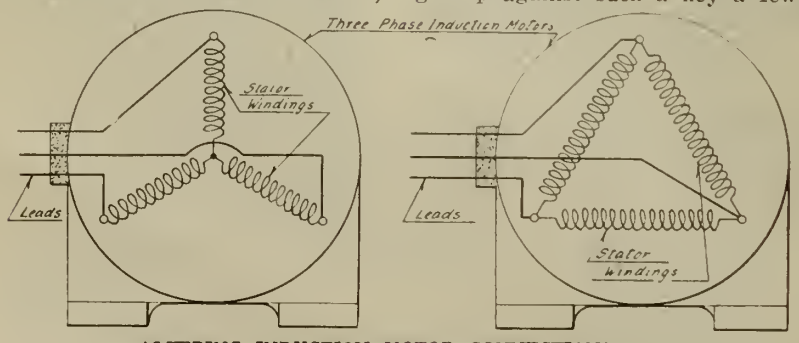
For ammonia piping, a cement made of litharge and glycerine is used. Sufficient glycerine is added to the litharge to provide a plastic putty. In using this cement only enough should be made at each mixing for one joint, because it sets very rapidly. It should not be disturbed after having once set.

RECONNECTING 440-VOLT INDUCTION MOTOR FOR 220 VOLTS

By B. Hermann

(Copyright. All rights reserved.)

If a 3-phase, 60-cycle, 440-volt, squirrel cage induction motor has its stator coils connected in star (Fig. 1) as it probably has, it can, possibly, be made to give satisfactory service on 220 volts, if its windings be connected in delta as shown at Fig. II. If the starting torque required is great the scheme will not work. But if the starting torque is only about three-fourths of the full load torque the motor will operate and give good service on 220 volts, if it is connected as shown at II. It will then have,



ALTERING INDUCTION MOTOR CONNECTIONS.

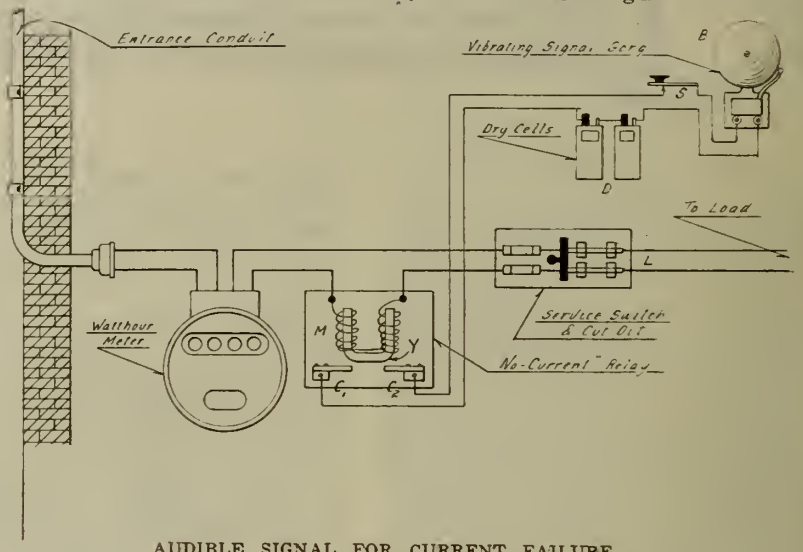
at 220 volts, practically the same horsepower output, power factor and efficiency as it did when operating star-connected at 440.

AUDIBLE SIGNALS TO INDICATE DISCONTINUANCE OF LOAD

By Richard L. Dyke

(Copyright. All rights reserved)

The signal will ring when a group of motors in a distant building is stopped. Fig. 1 indicates the connections. A relay, M, was made and connected to the circuit which supplies the load. When the load is taking current through the line L, the magnet coils of M have current in them and pull up the U-shaped yoke Y. But when the load is discontinued, Y drops down and makes contact to cross C_1 and C_2. This closes the electric bell circuit and causes B to ring, and it will continue to ring until switch S is opened. A large number of turns is not required on the magnet coils, M, as their function is merely to hold up the yoke Y. It is not, in most cases, necessary that the magnet coils be sufficiently strong to pull up Y because it can be raised by hand. The wire used for the magnet coils, M, must be of great enough size to carry the full-load current in the circuit.



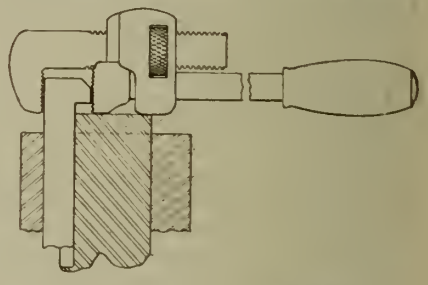
AUDIBLE SIGNAL FOR CURRENT FAILURE.

POWER PLANT KINKS

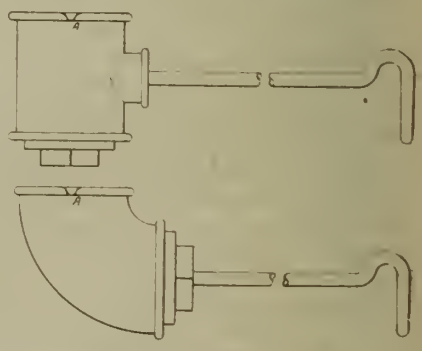
By J. E. N.

Many keys are driven in so tight that it is a difficult job to get them out. I got up against such a key a few days ago and tried the old stunt of placing a monkey wrench on to it and driving a wedge under the cut at the head of the key; however, at every heavy blow from the hammer the wrench would spring off the key head. I discarded the monkey wrench and used instead a Stilson pipe wrench as shown in the cut. This hung on like grim death until I got the key started. This is only a small tip but sometimes a fellow will fail to think of just such little things.

Another little kink is to make a babbitt pouring ladle. Fig. 2 shows such a ladle made from a 2½x2½x¾ tee, a plug being in one end, a pouring lip being filed on the top rim at A, and a piece of



REMOVING STUBBORN KEY



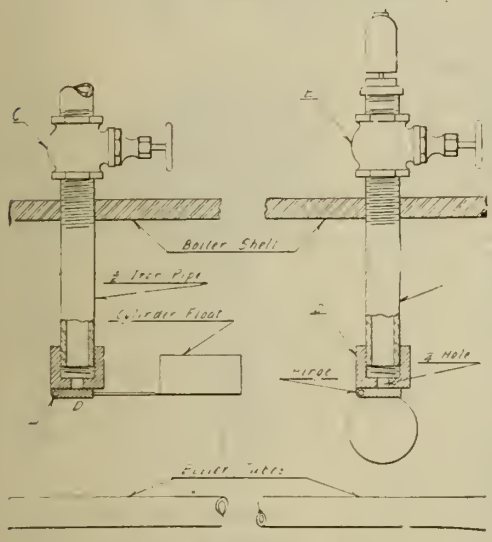
EMERGING BABBITT LADLES.

1 in. iron rod being used as a handle. Fig. 2 shows an elbow being used for the same purpose, in this case a plug is drilled and tapped to take in the rod for the handle, or a bushing the right size can be used. In either case the handle must be screwed in very tight so there will be no danger of it turning while pouring the metal.

LOW WATER ALARM

In Figs. 1 and 2 are shown a low water alarm designed by the writer. The valve, whistle and pipe are ½ inch in size. The valve, D, is a very simple affair as shown.

If a larger pipe than ½ inch is used I would suggest using the float shown in Fig. 2. It can be made any diameter required, and the longer the float and the attaching rod the greater the leverage, but care must be taken to attach the rod very firmly to the float. These floats must have enough weight with leverage to overcome the force of the pressure holding up against the small flap at D, Fig. 2. The hole in the bottom valve should be about ¼ inch, the diameter of the covering piece being about ½ inch.



LOW WATER ALARM.

The handle should be removed from the valve over the boiler. A better plan would be to lock the valve open. The sketches show everything so plain that further written description seems unnecessary.

JOHN THORN.

SUPER-POWER PLANTS IN GREAT BRITAIN

The recent decision to proceed with the super-power station scheme for electric supply in Great Britain calls to our notice what should be done along these lines on a more modest scale in certain portions of Canada.

The British plan to improve the supply of electricity throughout Britain contemplates the replacement of the numerous small stations now in operation by fewer but much larger stations supplying the extensive districts through high tension transmission networks. There will be a gain both in economy and fuel conservation and, in many cases, the quality of service will be much improved. This national electric supply operates under the supervision of five commissioners appointed by the Board of Trade; these, in turn, appoint district boards which include representatives of electric undertakings, of large consumers and of labor.

Lancashire is to be one of the first areas dealt with, the country being divided into three districts. Some of the smaller stations will probably be shut down immediately, the energy transmitted from larger existing stations being substituted. Following the building of the new super-power plants, the Commissioners will eliminate the remaining small stations and also the moderate-sized plants.

A similar situation, however, does not occur in Canada, as by far the larger portion of the capacity of our hydro-electric stations is to be found in what may be called "super-power" stations; many of them are also interconnected to allow more efficient operation.

There is, however, a portion of Canada where the absence of water power makes it necessary to supply power from steam or other fuel agencies. This area, which comprises southern Saskatchewan and adjacent portions of Manitoba and Alberta, is becoming of much importance through its rapid agricultural expansion, and its future needs should be anticipated as far as possible.

As pointed out in a report on Electric Generation and Distribution in Canada, recently published by the Commission of Conservation, adequate supply of electric energy in this section is confined to a few large centres. The smaller municipalities have installed small electric plants which are usually very expensive to operate and only give a night service. The rates which have consequently to be charged and the limited service prevent the full benefit which should otherwise be enjoyed from the various uses of electric energy. All these small plants through concerted action could be replaced by a few large and more efficient ones, each supplying a fairly extensive district by means of electric transmission lines. The cost of production would be reduced to about one-third and a better service supplied.

The example given in the above-mentioned report illustrates the possibilities in the Estevan district. A central power plant at Estevan would supply transmission lines radiating in various directions covering a total length of 150 miles. The estimated demand, based on the requirements of the near future, shows a total of some 600 h.p. outside of Estevan. As the lines would only carry a light load they could be built cheaply with light conductors and at a cost possibly not exceeding $2,500 per mile. If we allow a load factor of 40 per cent. the cost of transmission would average 2½c per k.w.h. The cost of production in the central plant would be from 2½c to 3c per k.w.h., so that the electricity could be delivered for an average of from 5c to 5½c per k.w.h. at the various small centres supplied. With a small plant, the present cost runs as high as from 15c to 19c per k.w.h. Numerous other districts, if treated in the same way, would probably show advantageous results.

ELECTRO-PLATING ON IRON FROM COPPER SULPHATE SOLUTION

For electro-plating on iron or steel from a copper sulphate solution, platers have in the past found it necessary either to give the metal a preliminary coat of nickel or to plate it with copper from a cyanide solution before transferring the object to the copper sulphate plating bath. Since the sulphate solution is much more satisfactory than the cyanide for the production of heavy deposits of copper, where these are required the plater has been compelled to maintain two different plating solutions, and to perform two distinct plating operations. The desirability of being able to plate directly on steel in the copper sulphate solution is apparent, and many persons have tried to discover a method of doing so, but until recently without success.

It has been discovered recently that by immersing iron for a few moments in an acidified solution of arsenious oxide, an adherent copper-plate may be deposited from an acid electrolyte, but no adequate explanation had been offered for this unique effect of arsenic. In this paper it has been shown that certain solutions of lead and antimony may be substituted for the arsenic dip, previous to direct-current plating of copper on iron from copper sulphate.

It appears to be impossible to obtain a perfect plate on iron from solutions of bismuth chloride by the usual methods of electro-plating, but use of the arsenic or antimony dip is attended with the same successes as in copper plating.

The successful substitution of solutions of antimony and lead for arsenic, and the application of these dips to plating on iron with bismuth, show that the beneficial effect of the arsenic dip is not due to a property peculiar to arsenic alone, but is the result of coating the iron with a metal whose potential in acid solutions is so near to that of copper that it is possible to deposit a good copper plate upon it, yet whose potential is not so far below iron that it will deposit on iron in a powdery, non-adherent form.—O. P. Watts ("Proceedings of the American Electrochemical Society.")

QUESTION BOX

(Continued from page 374)

have an efficiency of 87 per cent. The factor of safety is 5?

Answer.—The allowable working pressure equals: $60{,}000 \times .87 \times 2 \times 11\text{-}32 : 60 = 119.6$ lbs. per sq. in.

Question 59.—If 2½ in. stay-tubes are placed 10 in. centre to centre, what area will each tube support?

Answer. — Area $10 \times 10 - 4 \times 2\frac{1}{2} \times .7854 = 80.37$ sq. ins.

Question.—61. With a steam pressure of 160 lbs. per sq. in., what load is borne by each staybolt if the pitch is 7 in.?

Answer.—Load $= 7^2 \times 160 = 7{,}840$ lbs.

Question.—62. To what distance beyond the top of the upper row of tubes may the head conservatively be estimated to be supported by the tubes?

Answer.—A distance equal to one-half the width of the bridge.

Question.—63. For what reason is the furnace of a vertical boiler made of light plate and stayed?

Answer.—Heavy plates greatly retard the transmission of heat from the fire to the water.

Worth-While Information From Many Points

The number of German airplanes destroyed by the French aviators and the members of the Lafayette escadrille for the ten months ending October, 1917, was one hundred and twenty over the French lines, and three hundred and ninety-seven over the German lines—all total wrecks.

* * *

Shoe soles with metal coverings were made by Germans during the war—leather, cardboard, or wooden soles covered with aluminum or iron, not more than 0.01 mm. thick. The weight was the same, but they lost flexibility, became more solid and quite water-tight.

* * *

An English scientist declares that insomnia may be cured by removing excess moisture from the lungs. To put his theory into practice, he has devised a small machine for supplying warm, dry, filtered air, which the patient then breathes through a nose tube secured to the head with tape. The process is said not to be uncomfortable.

* * *

Saving controller contacts from damage by arcing is the object of a European inventor. In series with the contacts he connects hot-cathode rectifier tubes, whose heating circuit is broken by the switch arm in advance of the main circuit. The momentary interruption of the current prevents any arc formation.

* * *

The hardness of water is usually expressed in degrees, one degree being equivalent to a solution of one part by weight by carbonate of lime or other hardening salts to one hundred thousand parts of water. Wells generally contain the hardest water, 35 degrees of hardness being common. With water of one degree of hardness, the water contained in a single big tender would deposit 75 lbs. of mud or scale-making sediment.

* * *

A jackshaft or conveyor, if driven by a belt, may give a warning of its own stoppage by the use of an electric-bell wire with push button, and over it a piece of slat, held up by a spring. Place these so that if the belt comes off, part of its weight comes onto the slat, thus depressing the push button and closing the circuit. This may be used with either horizontal, vertical, or inclined belts, provided the surroundings permit the installation of wires and push-button support at suitable points. More than one bell may be wired up, each with its own circuit and its own push button beneath the slat, or several buttons may be connected through the signal lights to the same bell.

* * *

Enquiry has been made recently as to the possibility of the Mahwa tree, a native of the warmer parts of India and Burma, being cultivated in Europe. The reason of the enquiry is not a wish to introduce a tropical plant as a curiosity, but because the tree bears a flower which produces 90 gallons of 95 per cent. alcohol per ton.

* * *

A chimney has been built in the United States at Cleveland, for the Cleveland Electric Illuminating Company. The chimney, which is 163 feet high, is on top of the power house. The chimney at the top is 20 feet internal diameter, and the thickness of the wall is 10 inches, while at the bottom the thickness is 20 inches and the outside diameter is 43 feet. The weight of the whole structure is 1,200 tons, and this is supported on a concrete stage, having 12 legs reaching down through the building. The height of the stage above the basement in 105 feet.

* * *

The total number of electricity generating establishments in the United States in 1917 was 6,541, 4,224 being private and 2,317 municipal undertakings. The total primary power in 1917 amounted to nearly 13,000,000 horsepower—an increase of 70.8 per cent. as compared with 1912. Of this power about two-thirds was derived from steam and about one-third from water, the slight surplus being obtained from internal combustion engines. The total dynamo capacity in 1917 was, roughly, 9,000,000 kilowatts, 74.3 per cent. more than in 1912; while the output of energy aggregated 25,500,000 kilowatt-hours, an increase of 119.9 per cent. for the period 1907-12. It is stated, incidentally, that incandescent electric lamps are rapidly exceeding arc lamps for street lighting.

* * *

The engineer surveyor-in-chief to the British Board of Trade, in making a report on the explosion of a tube in a Babcock and Wilcox water tube boiler found that the "tube failed in the ordinary course of working, apparently through deterioration through long usage, it being one of the original tubes fitted in the boiler some twenty-two years ago. It would probably have been very difficult to have detected the defective condition of this tube before it burst, but in view of what has now happened the condition of the material of the remaining tubes should be ascertained by withdrawing some of them for a bending test.

* * *

Careful experiments as to the permeability of concrete have disclosed the fact that for heads up to 24 feet, it is impermeable for oils of low gravity. Concrete tanks for fuel storage have been built without any special precaution beyond the washing of the concrete with a rich cement mortar immediately after the removal of the forms. In some cases a solution of sodium silicate or water glass has been used.

* * *

The use of reinforced concrete for the repair of masonry bridges, which through age, excessive traffic or other causes, have decayed or been damaged, is now recognized by engineers in England as a very effective method and one which dispenses with the necessity of rebuilding. A number of England's highway bridges that for various reasons would have needed reconstruction have been made good by the employment of reinforced concrete.

* * *

That the aeroplane engine is not above ordinary humdrum work is shown by the fact that one has recently been installed in a London factory as a stand-by power unit. It burns gas instead of petrol and the cooling water is circulated through a common cast iron radiator. It is an eight-cylinder engine, surplus from the war, and at the aerial rate of living would develop 200 horsepower, but has been rated at 75 horsepower on earth to give it a reasonable length of life. The space occupied by the engine is only 8 ft. by 5 ft., by 5 ft. high, while its weight is about 800 lbs.

* * *

At Portland, Oregon, a gas container 70 feet in diameter and 75 feet high, weighing 300 tons, was moved a distance of three miles. First, it was raised 15 feet and loaded on rollers. Then it was moved four blocks through the city streets and lowered 28 feet to a dock, whence it was moved upon a pair of barges. The barges were towed three miles to a shipbuilding plant, where the tank was unloaded and raised 26 feet, moved across newly-filled ground for a distance of 2,000 feet, crossing a railroad track and placed on its new foundation. It took 71 days to complete the work.

TRADE GOSSIP

To Manufacture Fish Leather.—An American firm has been looking over the ground in Kingston, Jamaica, with a view to establishing a tannery for fish hides. The skins used would be those of sharks and other non-scaly fish.

Mjor A. G. Hutter has taken up the management of the Montreal office of the firm of Wonham Bates & Goode, Inc., New York and London, exporters and importers. Previous to going overseas Major Nutter was connected with Mussens, Ltd.

Railway Shop Busy. — The Leaside shops of the Canadian National Railway are pretty busy these days. There are about twenty locomotives in the shops for repairs besides several coaches. About 300 men are employed at present, and skilled mechanics are being taken on daily.

May Purchase Towers.—It is reported that the Nova Scotia Steel and Coal Company have started negotiations for the purchase of the coaling towers at the Halifax terminals, now the property of the British Ministry of Shipping, and also for the purchase of a large supply of coal now on the piers.

New Cable Line.—As a result of the long-felt dissatisfaction with the Pacific cable service between the U. S. and Japan, a group of Japanese business men are floating a company with a capital of about $25,000,000 for laying a new cable line. American capital will likely be enlisted as well as Japanese.

Motion to Wind Up.—A number of the shareholders of the Imperial Steel & Wire Company having made an application for the winding up of the company, Mr. Justice Kelly has adjourned the application to September 11th. In the meantime he has appointed Mr. G. T. Clarkson to make an examination into the affairs of the company.

Kingston Wants Elevators.—Kingston is going to make a bid to be the grain transhipment port in place of Port Colborne. The city council is going to urge the Dominion Government to build large elevators there. They point out that it will take two years to rebuild the elevator at Port Colborne and by that time the Welland Canal will be finished and Kingston will be the logical point for the steamers to bring their grain cargoes.

The Green Engineering Co., Chicago, announce that the firm of Bull & Swensparger have been appointed as their sales representatives in Chicago and northern Illinois territory. They will take charge of the Chicago office of the company on August 1. Mr. E. H. Bull has been connected with the Green Engineering Co. as an engineer for the past seven years. Mr. D. A. Swensparger has been a member of their sales force for the past nine years.

Halifax, N.S.—The Public Utilities Commission has granted the Nova Scotia Tramways & Power Co. permission to issue $2,000,000 in notes. The company contemplates extensions and improvements this year to its tramway lines, involving an expenditure of about $1,000,000. The proposed work will include the installation of new equipment in power house, extensions of lines, the purchase of new cars, etc.

St. Raphael, Que.—Plans have been completed by Gauvin and Lessard, engineers, 14 Cote de la Montagne, Que., for a water power development at St. Raphael for La Corporation Electrique de Montmagny. The engineers, it is reported, would like to receive prices on equipment for proposed plant, including two waterwheels with a rating of 1,100 h.p. each; head 245 feet. Also for two generators, exciters, switchboards, penstock, 8,020 ft. long, one headgate and construction of 3-phase, 55,000 volt transmission line, 16 miles long.

Trade Commissioner's Views.—The Canadian Trade Commissioner from Manchester, England, has been visiting Toronto, and has some interesting things to say anent the prospect of trade with Great Britain. He states there will be a good market for Canadian manufactured goods and raw materials in the Old Country for the next three or four years, and gave instances of orders recently placed by English firms in Canada. He mentioned a half million dollar order for confectionery placed by a Manchester firm in Canada, besides huge orders for rivets, wire nails and wire. There is a shortage of three-quarter million homes in Great Britain, and enormous quantities of windows and doors would be required.

BOILERS FOR SALE

ALL IN EXCEPTIONALLY GOOD CONDITION —17 Atlas Horizontal Tubular Boilers (Babcock & Wilcox), 60 inch by 16 feet, with Jones Underfeed Stokers; Boilers lying at Kitchener. 1 350-H.P. Erie City Boiler. 4 250-H.P. Scotch Marine Boilers with wet heads, now lying at Wallaceburg plant.

Western Association of Mechanical and Electrical Engineers

Edmonton District Loop No. 5

This Association would be pleased to receive correspondence from any engineers who would like to associate with us with a view of getting better conditions for the craft in general. We would also be pleased to have communications from any other society or societies of engineers who are endeavoring to secure these conditions. Address all communications to

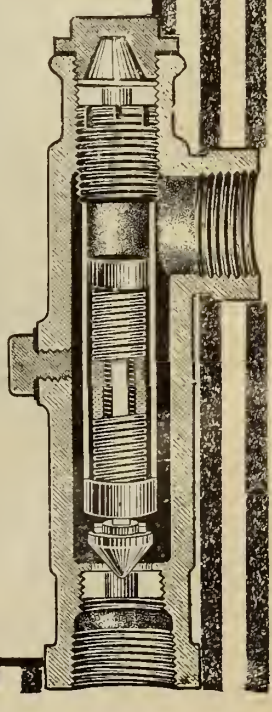
The Secretary,
Western Association of Mechanical and Electrical Engineers.
P.O. Box 991, Edmonton, Alberta, Canada.

THREE STEAM TRAPS FOR COST OF ONE!

There is no more excuse for using high-priced, cumbersome, leaky, inefficient traps of the bucket or float type than there is for obsolete, time-wasting mechanical equipment in your plant.

The Steam Trap Sarco costs about one-third the price of other traps and is a distinct advance in steam trap design.

When condensation gathers, the expansion element opens the valve automatically, allowing the water to run off. And the minute the moisture drains off the valve closes. No waste of steam.



Steam Trap SARCO

has only one moving part—no levers, gauges, packing, stuffing boxes, etc., nothing to adjust or get out of order.

And on account of its smallness you can install the Sarco in limited space where ordinary traps wouldn't fit on account of their size. Does away with digging a pit or building a platform.

Guaranteed for any given pressure up to 200 lbs. Hundreds of thousands in use.

A thirty days' Free Trial of the Sarco will give you new ideas of steam trap efficiency. No obligation. Write to-day; also ask for Booklet "J."

Scene in the Haley Mill Showing Goodyear Extra Power Belting in Use.

Another Convert

HALEY & SON,
Lumber Merchants

Gentlemen:—

We want to tell you about the Goodyear Extra Power Rubber Belting we bought for our new mill two years ago and what great satisfaction this Belting has given us. As you are aware, we bought this kind of belting from you for the equipment of our mill **throughout,** even to planers and matchers. We were skeptical at the time about using this belting on our matchers, especially on the side heads, as that is a very trying place for any kind of a belt. We concluded we would try your rubber belting, as we thought then as a makeshift. Now it has been something over two years since we belted up our matchers with your belting and the original belts are yet on these machines and still giving good service. We thought where this belting of yours had proved so eminently satisfactory that we should tell you just as we thought about it and you know we are giving you this testimonial of Goodyear Extra Power Rubber Belting entirely at our own initiative.

Yours truly,
HALEY & SON.

GOODYEAR
MADE IN CANADA

Almost Unbelievable Power-Saving and Economy

Time and again we have found purchasers of Goodyear Extra Power Belting openly skeptical that it would live up to our promises.

Time and again they have told us not only of lower belting costs, but also of increased and faster production, time and power saved.

To-day there is no reason for any plant to buy belting on promises.

On file in our office are letters which enable you to buy belting by proof.

Records of Goodyear Belting performance.

Records of extreme long-life, which means economy.

Records of pulley-gripping, non-slip qualities which save power.

Records of work under strenuous conditions of heat, cold, damp, acids.

Records of strength and flexibility.

Records which prove that without Goodyear Extra Power Belting enough power is wasted in Canada every year by poor belts to pay a big dividend on Industry's capital.

Some of this power is being wasted in your plant. Better belting, scientifically applied, will save you money. Without obligation to you, a belting man, trained by Goodyear, will call and make a record of your needs and experiences. Our recommendation will come from engineers who fit belts to conditions. Phone, wire or write the nearest branch.

NATIONAL Boiler Girth Seam Protector

Protection means longer life and greater efficiency

If your Boiler is not Fire-cracked it eventually will be. Prevent this by putting on a National Boiler Protector. You will save cost in repairs and prolong life of the boiler. All new boilers should be protected. If your girth seam is giving you trouble at the present time, have the seam caulked up, attach one of these protectors and the seam will remain absolutely dry thereafter.

Guaranteed for one year. We make protectors for patches and all styles of boilers. For full particulars, write—

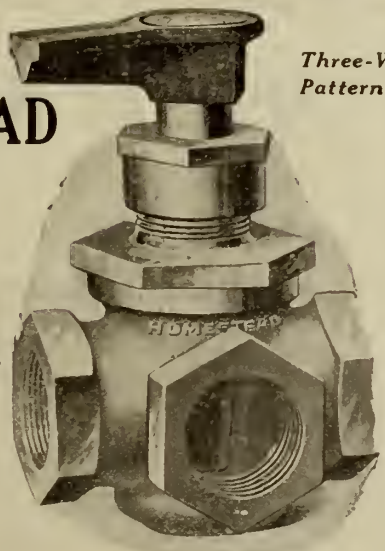
HOMESTEAD

Quarter-Turn Valves

Three-Way Pattern



Economy!
Efficiency!
Safety!

The efficient service Homestead Valves give, proves the superiority of plug cock valves over other types. Homestead Valves combine direct and unrestrained flow with simplicity and ease of operation.

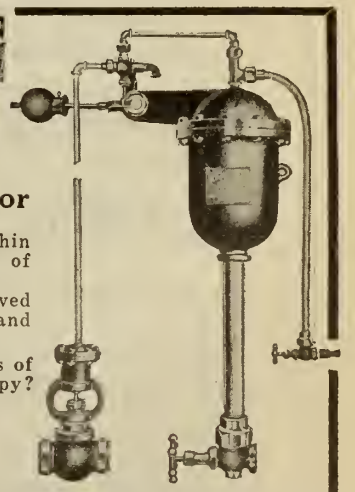
Every Homestead Valve saves its own cost shortly after installation by eliminating wastes and leakages. This is an economical feature of Homestead Valves worth considering.

The harder the service, the more the safety of Homestead Valves is appreciated. Easily stand greater pressure than that for which they are recommended.

HOMESTEAD VALVE MFG. CO.
HOMESTEAD, PA.

VIGILANT

Automatic Feed Water Regulator



The "Vigilant" keeps water within ¼" of middle gauge regardless of load or firing.
Years of service test has proved it the utmost in reliability and efficiency.

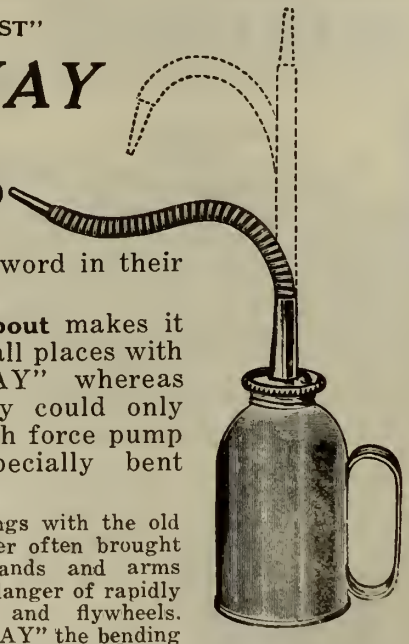
"SAFETY FIRST"

ALL-WAY
RAILROAD
OILERS



are the latest word in their line.

The **flexible spout** makes it possible to oil all places with one "ALL-WAY" whereas previously they could only be reached with force pump cans with specially bent spouts.

Lubricating bearings with the old straight spout oiler often brought the engineer's hands and arms very close to the danger of rapidly revolving gears and flywheels. With the "ALL-WAY" the bending of the spout removes this danger.

Sizes No. 4, 1 pint—10 in. spout. No. 5, 1 quart—11 in. spout.

Flexible spouts can be furnished for any kind of oiler. If your dealer cannot supply you write us.

We also manufacture the well-known "All-Way" Oil Can—saves you 50% of your oil bill.

THE ALL-WAY OILER MFG. COMPANY
196 KING STREET WEST - TORONTO, ONTARIO

The Secret of the Strikes

Most Canadians are asking "What is the cause of the 'Great Unrest' "? Is it the fault of labor—or of capital?—or is it the result of German propaganda? Do you know of the real reason for the labor disturbances in Canada, and elsewhere? Are YOU thoroughly familiar with the ins-and-outs of the plans which threaten a world-wide "tie-up?" This is something that should be understood by every Canadian. And every Canadian should read "The Secret of the Strikes," by Lieut.-Colonel J. B. Maclean in the August issue of MacLean's Magazine. It is brimful of startling and authoritative information regarding this great problem. Read it carefully. It starts on page 33, August MacLean's.

"The Lecturer At Large"

Stephen Leacock is one of the continent's greatest humorists. "The Lecturer at Large" is one of the best humorous sketches that he has written. It is made up of what he terms "a few painful reminiscences of the platform" in the course of his lecturing up and down Canada. Get your family around you and read the sketch aloud—it's a rare treat.

Other Big Features

"A Party in the Making." By J. K. Munro. Illustrated by William Casey. An article on the political situation, giving a great deal of inside information with reference to recent developments at Ottawa.

"Solving the Problem of the Arctic." By Vilhjalmur Stefansson. The fifth instalment of his story of the five years' explorations that he conducted for the Dominion of Canada.

"The Unspoiled Country." By Harold C. Lowrey. A descriptive article of a part of Canada which is little known to Canadians generally, Temagami.

"Petite Simunde." By Arthur Beverley Baxter. Illustrated by E. J. Dinsmore. A charming romance of the war. The author will be remembered favorably for his "Mr. Craighouse of New York, Satirist."

"The Seven Blue Doves." By W. A. Fraser. Illustrated by Charles L. Wrenn. The fifth of the Bulldog Carney series and in some respects the best. It is a mystery story.

"His Majesty's Well-Beloved." By Baroness Orczy. Illustrated by C. F. Peters. The second instalment of this splendid romantic novel of the colorful era of Charles II.

The Month's Vital Question

Turn to page 34, August MACLEAN'S, and you will find timely and interesting information regarding the High Cost of Living—a problem of large proportions.

The Review of Reviews

Here are a few of the articles chosen as the best published during the past month in all magazines:—Britain Winning Supremacy of the Air; Has Japan Two Governments?; Kaiser Employed Famous Beauties; The New Triple Alliance; Mammoth Animals in Alberta.

Over 70,000 Canadian Families Buy

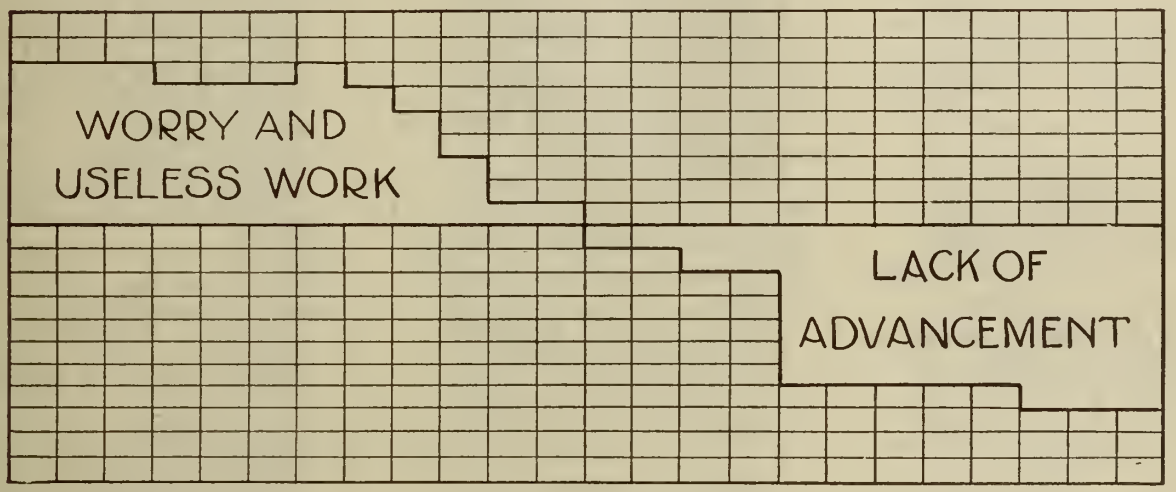
Let the C.A.S.E. Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

BOILER INSPECTION

The Steam Boiler Act, Chapter 252 R.S.O., 1914, With Amendments Chapter 58—6, George V.

STEAM BOILERS

All Steam boilers constructed for use in Ontario must be built from designs which have been approved and allotted a registration number by the Steam Boiler Branch.

Used boilers, boilers sold or exchanged, and unregistered boilers brought into the Province must be inspected prior to being put into operation.

Notice of repairs to steam boilers, stating the nature and extent of same, must be sent to the Steam Boiler Branch, and should such repairs be considered extensive by the Chief Boiler Inspector, the boilers will require to be inspected.

In each and every case the inspections must be made by Inspectors authorized to inspect boilers under the Steam Boilers Act, who are employed only by the Steam Boiler Branch of the Department of Public Works. Official certificates with the maximum working pressure stated thereon are issued to the owners of the boilers so inspected.

STEAM PIPING

Drawings and Specifications of all high pressure steam piping must be approved and registered by the Steam Boiler Branch before any work of installation is commenced. The drawings submitted should show clearly the dimensions and layout of the main steam lines. Full particulars should be given as to the material used in the construction of the piping, and all valves and other fittings used in connection therewith must be of approved make.

Any deviation from the above requirements shall be deemed a violation of the Steam Boilers Act.

All communications in this respect should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

HON. F. G. MACDIARMID, Minister of Public Works and Highways

W. A. RIDDELL, M.A., Ph.D., Supt. Trades and Labour Branch

D. M. MEDCALF,

Chief Inspector of Steam Boilers.

THIS IS TO SHOW YOU HOW
"Cole" Return Traps Save Your Fuel

ATTENTION, MR. ENGINEER:

Does your plant operate under these conditions? Just study this diagram a few minutes and we will explain to you how a "Cole" Return Trap System **saves your fuel.**

Don't you think this is rather an expensive method of handling your condensation? Warming up the outside air and damaging your drains, sewers, walls, etc.

Note the overflow from the tank. See the steam and vapour escaping to the atmosphere.

Look at the cold water jet cooling the hot returns as they enter the tank. This is all loss. Why can't this loss be avoided?

We can avoid this loss for you with our "Cole" Return Trap System. How? Let us explain.

You will note the average temperature of the returns in this case is about 266° F. The boiling point of water at 100 lbs. gauge pressure is 338° F.

The difference of the temperature of the returns at 266° F. and 338° F. at 100 lbs. gauge pressure is 72° F.

The difference in temperature of feed water at 160° F. to which we have cooled the returns down in order to enable the pump to lift the water and 338° F. the boiling point is 178° F. a clear loss of 106° F., or nearly 11% of the heat.

By putting it directly into boiler as hot as we can get it a "Cole" Return Trap saves this loss and handles the water into the boilers without robbing the boilers of steam to do it.

We will assume we have an ordinary Duplex steam pump pumping out of hot well. We all know a steam pump will not lift "real" hot water owing to the vapour in the suction pipe destroying the vacuum as fast as it can be created by plunger of pump. A pump's best work is to develop a horsepower at an expenditure of at least 120 lbs. of steam per hour, equal to 4 boiler horsepower. This 4 H.P. is wasted to the air when it might otherwise be doing useful work.

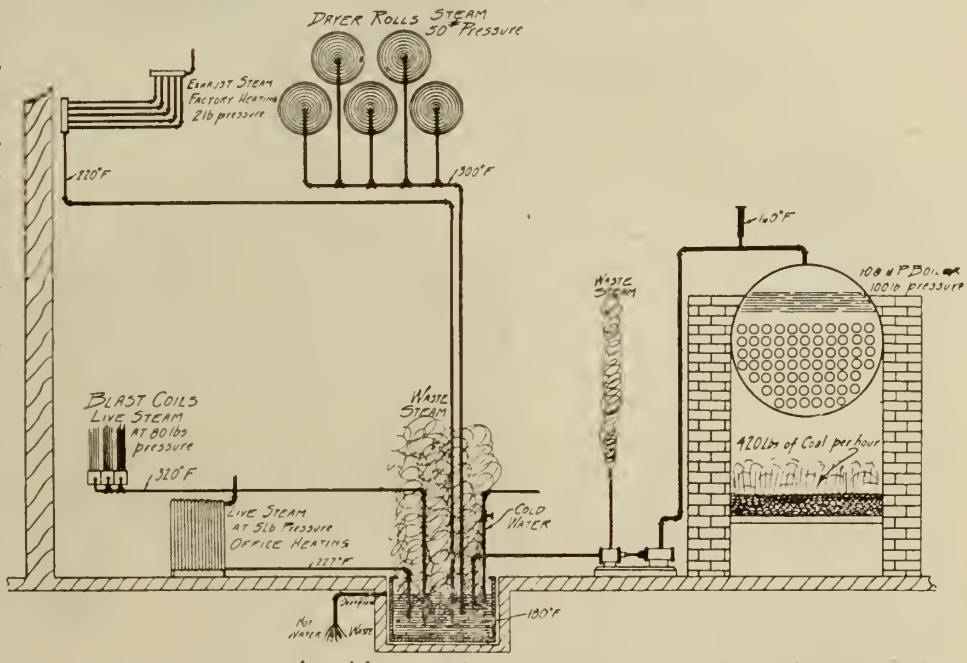
"Cole" Return Traps save all losses in condensation. With a simple installation of "Cole" Return Traps the water would be discharged directly back into boiler as hot and as quickly as it forms, to replace the steam going out of the boiler.

A Steady Water Line.—We would be getting pure distilled water back into our boilers, thereby greatly reducing scale formation, and saving as much useless work in boiler cleaning and much money for compounds and repairs.

We would be saving the cost and maintenance of boiler feed pumps, and also a considerable amount of fuel in making steam.

The Saving. By the installation of this equipment, you would appreciate the saving in your fuel consumption, your labor, and worry, as a "Cole" Return Trap needs a minimum amount of attention or upkeep. You would forget you had a "Cole" Return Trap installed owing to its smooth operation, no pounding of check valves or other objectionable noises, no packing of plungers, valves, etc. No attention to lubricators.

The Cost is nothing as compared to the saving effected with a good return trap system, in a plant operating under anything like this condition.

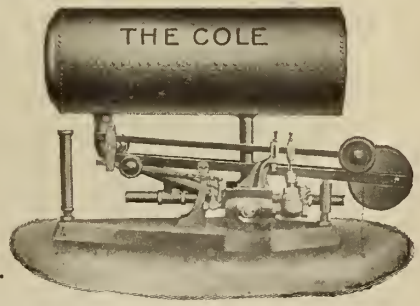


The savings effected would pay for such an equipment in a very short time, and as long as the plant operates the return trap system returns its cost over and over again to the owner.

Are you interested in the betterment of your plant conditions, Mr. Engineer? If so, let us help you.

Show your employer by your own practical engineering knowledge that you can save him money by the installation of a "Cole" Return Trap system suited to your requirements. He will appreciate you for it. He will know you are keeping in advance of the other fellow, by trying to modernize his steam plat and cut down his fuel bills. How about it, Mr. Engineer?

Write us for any information you require on the Cole Return Trap.



Stop the wasteful Steam Plants. Install "Cole" Return Traps. There is credit and increased wages in it for you.

GEORGE W. COLE, LTD.

2002-4 Dundas St. West - TORONTO, ONT.

More Data to Come.

In our next ad. we will illustrate other conditions which obtain in steam plants, and which you should be aware of, where constant losses are occurring, and which only need pointing out to the Factory Executive to have them corrected.

We have Bulletins, which contain interesting information to enquirers generally, and you should have them.

Write us for any further information on the "Cole" Return Trap.

"Beaver" Globe Valve.
Bronze.

The valve and seat can be furnished metal to metal regrinding, or with renewable copper disc. The seats are renewable and are fitted with set screws to prevent their working loose when the valve is in operation.

Particular attention is called to our improved joint between the body and yoke, the machined faces of the double spigot preventing any possibility of the gasket blowing out.

The stuffing box gland being made of bronze offers a non-corrosive surface for the stem and also prevents the gland breaking when the stuffing box is being packed.

Beaver valves have full area throughout.

Designed for a working steam pressure of 250 lbs. per sq. inch and are subjected to a hydraulic test of 500 lbs. per sq. inch before leaving our factory.

Write for full particulars.

How Dominion Rubber System Belting Service Helps Belt Users

For more than fifty years we have specialized in the making of belting and the solving of problems in transmitting power and conveying materials economically.

We maintain a staff of belting experts for the sole purpose of helping Canadian Manufacturers to "speed up" production by cutting belting costs and eliminating power wastage.

These experts will, without charge, analyze your transmission and conveying equipment in its entirety and will recommend changes only where they are necessary to increase the efficiency of that equipment.

You are under no obligation to us in availing yourself of this service — the only return that we request is that you purchase Dominion Rubber System Belting when you have been convinced that the changes recommended by our engineer will be beneficial.

This special service is available through any of our branches.

CASTINGS IRON and BRASS

These cast iron pipes ranging in size up to 24 in. in diameter and 14 ft. long, are representative of a large order of piping and fittings recently supplied the Brantford Water Commissioners.

The recent additions to our foundry have put us in a better position than ever before to supply your casting wants.

We supply grey iron castings up to 20 tons, also Brass, Bronze and Aluminum castings, either rough or finished.

You can be sure of their strength, smoothness and uniformity of texture, as we analyze all materials to insure a perfect product. The work is turned out true to pattern and readily machined.

POWER HOUSE, September 5, 1919, Vol. XII., No. 14. Published semi-monthly at 143-153 University Ave., Toronto, Canada. Subscription price in Canada, $1; in United States, $1.50. Entered as second-class matter at the Post Office Department, Ottawa, Canada. Entered as second-class matter July 1, 112, at the Post Office at Buffalo, under the Act of March 3rd, 1879.

PLAY SAFE

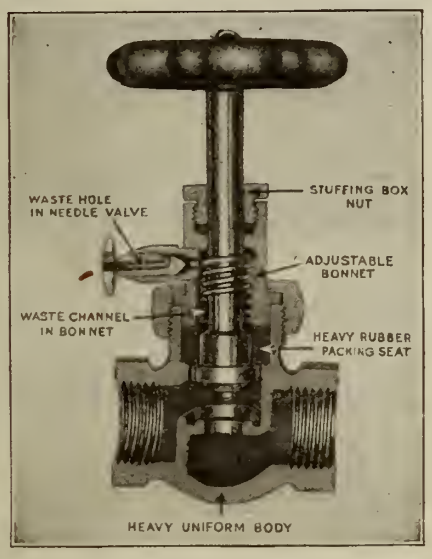

Plate A 840
Jenkins Disc Globe Valve

The whole steam system will be dubbed wrong if a faulty valve is installed, no matter how good the other fittings are.

The sanitary engineer cannot afford to have his good work reflected upon, by so small, yet so important, a factor of the work.

Make sure that the valve is right above everything else.

"Emco" valves are fitted with special high heat resisting "Radium" discs which last a lifetime.

They are registered in all provinces of the Dominion, our ordinary line being approved for 175 lbs. working pressure. All goods are thoroughly inspected and tested before they leave our factory.

Send for our catalogue. Specify "Emco" valves from your jobber or order direct from us.

HOMESTEAD, PA.

"Be Sure The JEFFREY Improved Carrier is Included in the Budget"

says the Chief Engineer

"You know that ever since the war started what a hard time we've had to keep men in the power plant. You see they did not like the hard, dusty job of wheeling ashes and with the opportunity of having easier work and better wages, you can't blame them for getting out.

"The tremendous job of reconstruction is continuing to create a great demand for labor. Another point to consider is that we are planning to overhaul the power plant completely. I am sure the JEFFREY Carrier will prove one of the best economies we have ever installed."

"By the way we should have Catalog No. 210-4 describing the Carrier on file here. I'll write for a copy to-day."

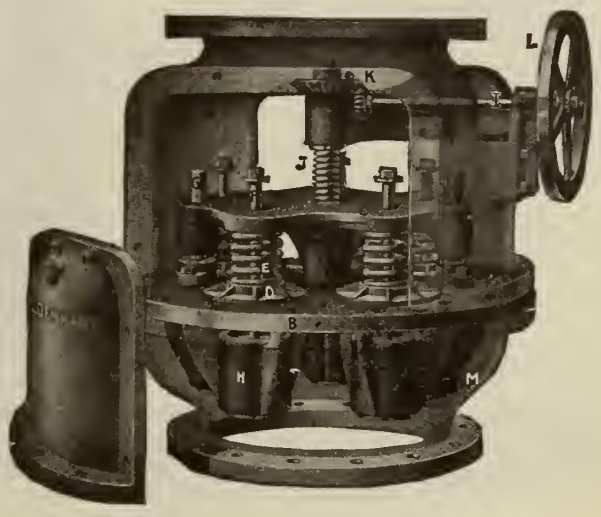
Some Pointers regarding the Cochrane Multiport

THE COCHRANE MULTIPORT

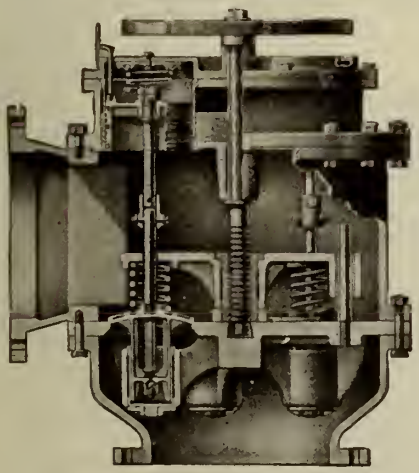
Is an improved Safety Valve
for the Exhaust Steam System

A UPPER CASING, having two removable doors, providing easy access to disks for regrinding, and to springs for removal, etc.
B VALVE PLATE, carries dash pots which guide and cushion the valves, and which are bored simultaneously with seats, insuring alignment.
C PRESSURE PLATE, motion limited to prevent exceeding a predetermined pressure.
D BRONZE VALVE DISKS. Cast integral with dash pot plungers.
E NICKEL-PLATED STEEL SPRING. Can be changed if a different back pressure is desired.
F BRASS LIFTING SPINDLES. Serve to lift disks off seats when exhausting free to atmosphere.
G BRASS SLEEVED GUIDE POSTS for pressure plate.
H DASH POTS. Bronze lining secured by nut on bottom.
I STEEL SHAFT for revolving bronze spindle; not required in horizontal form.
J BRONZE SPINDLE for raising and lowering pressure plate.
K BRONZE GEARS, not required in horizontal form.
L ADJUSTING HAND WHEEL. Valves are also arranged for control from distance by chains, extension shaft, hydraulic pressure, electric motor, etc.
M LOWER CASING.



Interior View, Fig. 1,000, Cochrane Multiport Safety Exhaust Outlet Valve.

WHEN used in back pressure service, it protects piping, radiators, feed water heaters, cooking kettles, absorption ice machines, low pressure turbines or other appliances, against abnormal rises in pressure whenever the amount of steam supply from the engine exceeds the ability of the exhaust system to condense or otherwise dispose of that steam.



Section of Cochrane Multiport Flow Valve for use in connection with Mixed Flow Turbine. Prevents condenser vacuum from backing up into the engine exhaust line and drawing in air through leaks, etc.

COCHRANE MULTIPORT VALVES for Vacuum Service are installed between engines or turbines and condensers. They serve not only to protect against abnormal rises in pressure, but they also provide a convenient and natural channel for the escape of steam during non-condensing operation. They are thoroughly water-sealed to prevent the entrance of air into condensers.

The main idea in designing the COCHRANE MULTIPORT has been to secure absolute safety by providing a number of channels of escape for the steam, so that the chances of all becoming inoperative at once are infinitesimal, at the same time doing away with the excessive list and severe hammering upon the seat inseparable from heavy single-disk valves.

In accomplishing this object, we have taken advantage of the opportunity to make the valve easily adjustable, that is, by varying the position of the pressure plate the tension of the springs may be adjusted for any back pressure desired. Where installed in connection with heating and drying system, it is thus often necessary to carry the maximum back pressure only for a few hours in the morning, while at other times the steam consumption of the engine is reduced by lowering the back pressure. With nearly all other valves, this is utterly impracticable.

The introduction of the pressure plate and spring principle into back pressure valve design also enables us to make the valves strictly foolproof, that is, it is impossible to overload or tamper with the valves, since the limited travel of the pressure plate determines the maximum back pressure. Inasmuch as there are no moving parts directly connected to the disks extending outside of the valve casing, overweighting, tying down or accidental obstruction are eliminated, likewise sticking through over-tightening of glands.

The method of control also makes it convenient to install appliances for operating the valves from a distance, as by means of a long shaft, a chain and sprocket wheel, hydraulic pressure, or by electric motor. That is, it is not necesasry to climb a ladder or to go up on the roof in order to change the back pressure, if you have a MULTIPORT. In atmospheric service, it is sometimes convenient to be able to open and close the valves from the switchboard, which can be arranged for with this type of valve.

In vacuum service, these valves offer perfect facilities for throwing over from non-condensing to condensing operation, especially in connection with reciprocating engines, since the engine may be allowed to exhaust through the valve until the moment when the main gate valve between the exhaust line and the condenser is opened, upon which the small disks will seat immediately without allowing an inrush of air thereby avoiding all danger of losing the vacuum and of having to prime the condenser over again. COCHRANE MULTIPORTS are built for all situations, that is, vertical pipes, horizontal pipes and angle pipes.

Special types of COCHRANE MULTIPORTS are supplied for preventing the vacuum from mixed flow turbines reaching back into the engine exhaust line, with consequent impairment of vacuum due to the drawing in of air through leaks in the engine exhaust piping, through piston rod packings, etc.

JOHNS-MANVILLE Mastic Flooring

Floors that resist time and tons

GOOD flooring is never bought on the basis of price alone. Other things, more important, must be considered. For instance, *maintenance cost.* Common flooring materials, such as concrete, wood, or asphalt, require frequent, costly repairs, and results are seldom satisfactory

Johns-Manville Mastic Flooring is "made to fit" any conditions and gives longest wear. Easily and quickly repaired—at little cost. When repairs are needed—simply cut out the worn or damaged section. Reheat this old material mixed with a small amount of flux—which we furnish; then relay. The new spot, flooded and rubbed down to the proper level, immediately becomes integral with, and has all the characteristic qualities of, the surrounding floor.

It is tough, durable and foot-sure, always; waterproof, quick drying and deadens noise. Johns-Manville Mastic Flooring is practically wearproof. Whether it faces the most mild or severe usage, its maintenance cost is always lowest.

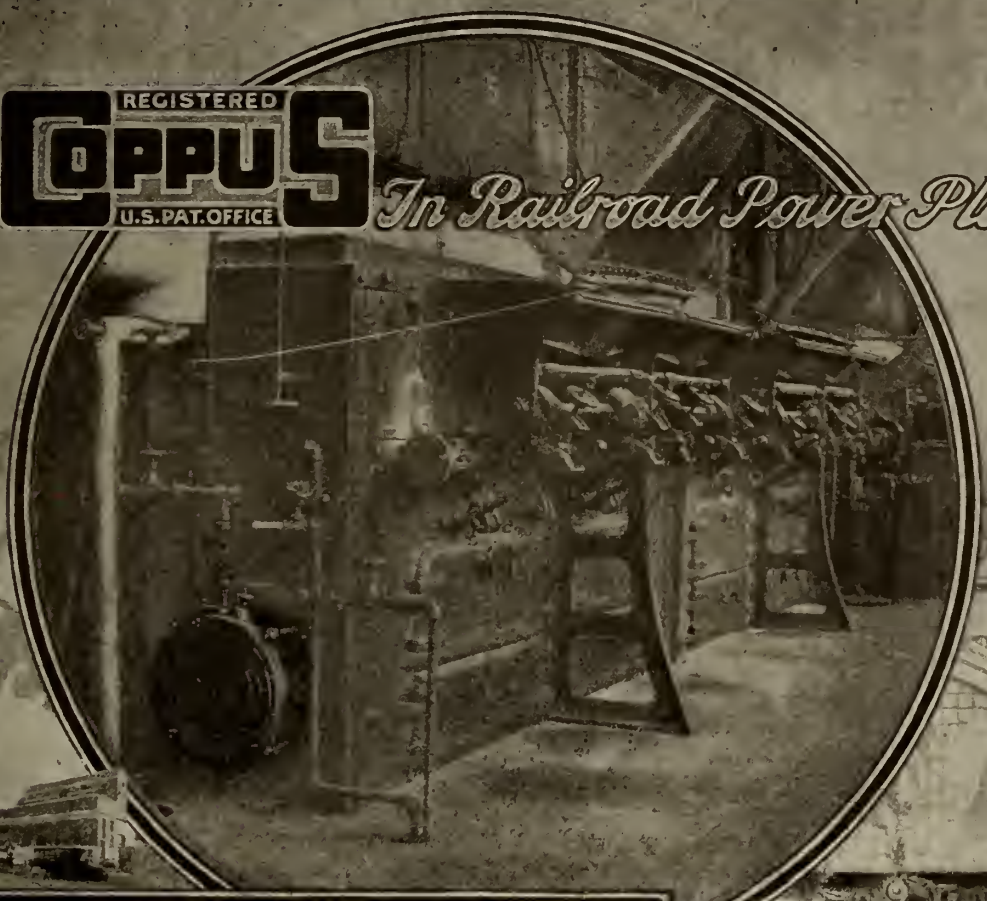
REGISTERED COPPUS U.S.PAT.OFFICE

In Railroad Power Plants



Railroads are sticklers for efficiency. Equipment approved by them must produce results—save money—earn dividends. The fact that the Central Railroad of New Jersey operates twenty-six COPPUS Turbo Blowers in their great shops at Jersey City —proves that these blowers **pay.**

Every one of this big battery of blowers—one of which is shown above—has cut coal costs—reduced labor charges—and saved dollars. In this power plant—as in thousands of others—COPPUS Blowers keep up steady steam pressure—prevent clinkering—meet peak loads quickly—and burn cheap fuel.

COPPUS Blowers **pay a profit** to the Central Railroad of New Jersey. **They can do as much for you.** Why not put them on the job? Catalog H-14 will show you how *"COPPUS Equipment can save you money."*

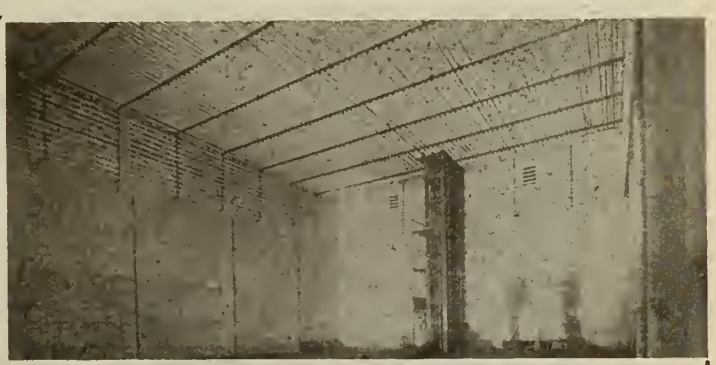
Are Leaky Walls, Floors and Ceilings Making Trouble for You?



5400-ton ice storage room of the City Ice & Storage Company, Kansas City, Mo., equipped with 130,880 board feet of Nonpareil Corkboard Insulation.

Trouble in maintaining the temperature of refrigerated rooms is too often blamed on the refrigerating machine when the real cause is inefficient insulation.

There may be nothing startling in this statement of fact; but, if such conditions prevail in your plant, what are you going to do about it? Are you satisfied to put up with all the annoyance that flows from leaky cold rooms; or have you had enough of this kind of trouble to convince you that it should be stopped?

So successful has Nonpareil Corkboard Insulation proven in preventing the escape of refrigeration from cold rooms that scores of owners have used it to supplant the insulation with which their plants were originally equipped. Changes of this kind are expensive, to be sure **—but not nearly so expensive as operating a plant with insulation that doesn't insulate.**

If you want to go down deep into the details of this product—if you want to know all the "whys" and "wherefores," send for the free book, "Nonpareil Corkboard Insulation."

In Canada's Biggest Industries

Where absolute certainty must be counted upon at all times, no chance can be taken with equipment.

In the big industries, especially must every detail be efficient—the blow-off valve as well as the boilers, pumps and engines.

So, when the big Canadian corporations such as the following instal Yarway (formerly the Simplex) "Seatless" Blow-Off Valves, their choice becomes an endorsement of the very highest character.

Canadian Explosives Co., Ltd., have 11.
Dominion Iron & Steel Co., Ltd., have 20.
Canadian Pacific Railway Co., have 24.
Bathurst Lbr. Co. have 8.
Montreal L., H. & P. Co. have 24.
International Eng. Wks., Ltd., have 13.

And there are many others. With the Yarway (formerly the Simplex) "Seatless" Blow-Off Valve there can be no sudden opening and closing to injure tubes; the operation is simple, certain and safe; the valve does not leak; it requires but little attention, as there are no weak places such as seats or discs to cut and scar; even the packing lasts for years. You can verify each of these claims by testing the Yarway on one of your boilers for 60 days. Return it if not satisfactory.

Write to-day, stating size of line, and whether screwed or flanged, angle or straightway.

Twelve eight-retort RILEY UNDERFEED STOKERS as installed under twelve 625 H.P.B. & W. boilers at the Port Morris Station of the New York Central R.R. Co.

One feature alone of the Riley Stoker—its moving grates—is worth a dozen skilled operators. Even the most skilled would find it impossible to keep the fuel bed free from holes and clinkers without dropping the efficiency by opening the fire doors.

The Riley Stoker moving grates distribute the fuel—keep the fuel bed open and porous—clean the fires—and discharge the ash and refuse. All done efficiently and economically without the attention of the operator.

It is this kind of money-making and man-releasing machinery that pays dividends, not only for the central station but for the industrial plant.

Your plant may offer large opportunities for saving. Investigate today. Complete details of the Riley Stoker construction are illustrated and described in Catalog HR-9. Copy on request.

For information on the Murphy Automatic Furnace for smaller boilers see advertisement in last issue or send for Murphy Catalog HM-9.

POWER HOUSE

Established 1907 Published Semi-monthly

Low Cost Hydro Power in Winnipeg

Interesting Facts and Figures Relating to One of Manitoba's Hydro-Electric Developments—The Winnipeg Electric Railway Develops Power at a Very Economical Figure

THE accompanying illustrations and drawings show the construction of the Winnipeg Electric Railway power plant which, with the Kenora and city of Winnipeg Municipal Hydro-Electric stations, form the most important developments in Manitoba to-day. The report of Chief Engineer J. T. Johnston, of the Dominion Water Power Branch of Ottawa, Canada, on the Winnipeg River power and storage investigations is of special interest, particularly on the possible power concentrations.

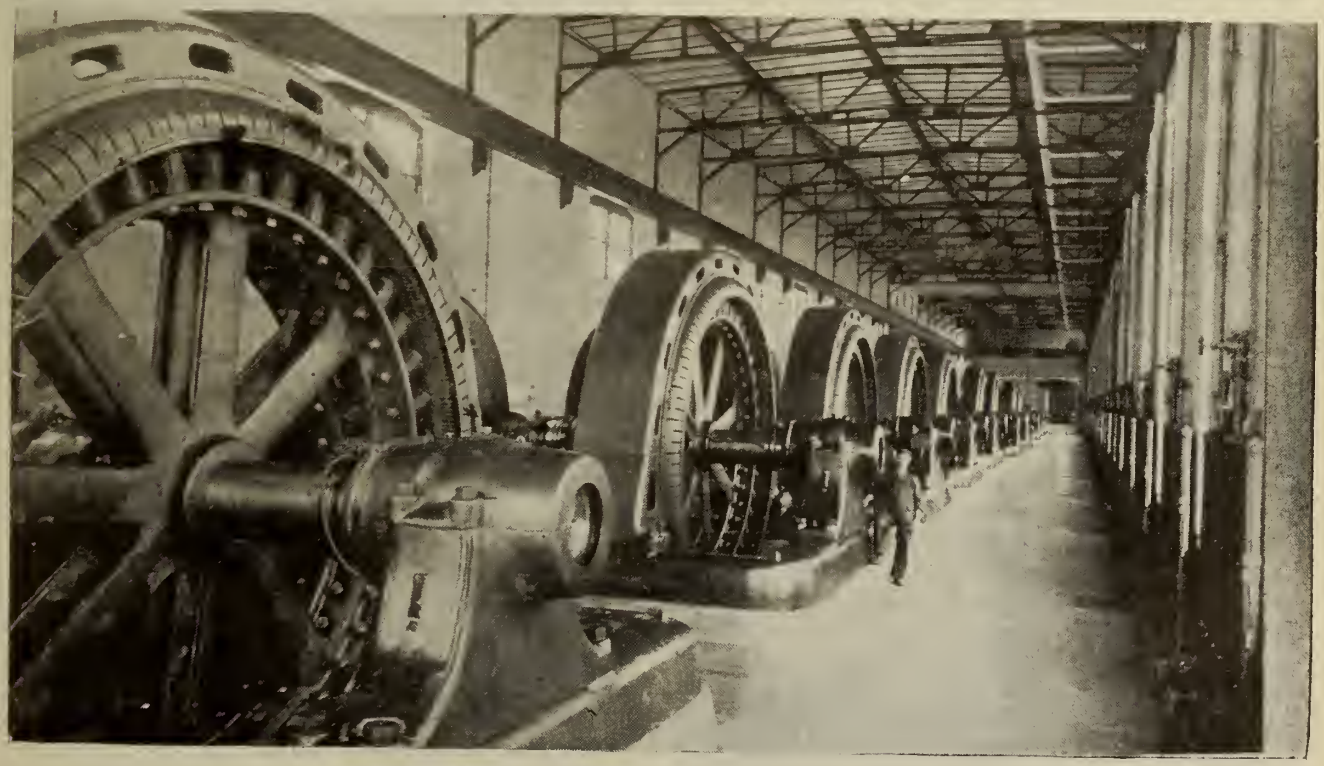
The following remarkably low figures are of interest as to the estimated cost of operation of the seven proposed power developments in Manitoba of Hydro-Electric power placed on the low tension switchboards in the power stations. It is pointed out that a consideration of the total costs shows the following: The total final output of the seven proposed developments is 313,500 horsepower at a total capital cost of $24,547,000, that is, an average cost of $78.30 per horsepower, or $42.80 per horsepower based on machinery installed, the mean annual cost being $5.48 per horsepower based on power output.

The detail estimates of the annual costs per horsepower of the seven Canadian developments are as follows:

	Per h.p. on basis of installation.		Per K.W. hour 100% load factor	
	12,000 Sec. ft.	20,000 Sec. ft.	12,000 Sec. ft.	20,000 Sec.ft.
Pine Falls	$ 5.05	$4.47	0.122	0.108
Du Bonnet Falls	15.04	5.54	0.116	0.102
McArthur Falls	7.24	6.40	0.166	0.136
Lower Seven Sisters Falls	.....	5.47	.....	0.132
Upper Seven Sisters Falls	.....	5.58	.....	0.138
Upper Pinawa	7.11	7.11	0.159	0.159
Slave Falls	5.70	5.21	0.131	0.117
Mean (based on power output)	$ 5.48	$4.21	0.130	0.118

It is stated that no consideration has been given to the cost of transmitting the developed power to the present industrial market, the reason being the uncertainty as to the use to which the power developed at the various sites will be applied. Undoubtedly in some instances the power will be used industrially directly at the site, either for pulp grinding or in connection with one or more of the various electro-chemical processes which are now coming to the front.

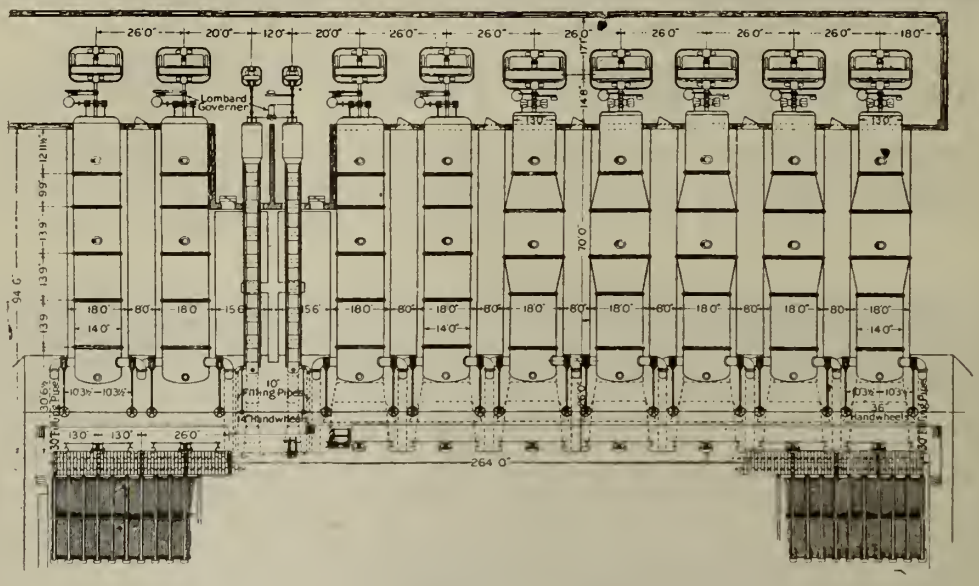
The entire reach of the river in Manitoba above Lac du Bonnet was more or less affected by the head-and-tail waters of, and the diversion conditions resulting from, the two existing undertakings. The river reaching below



INTERIOR VIEW OF POWER HOUSE SHOWING GENERATORS.

Lac du Bonnet was undisturbed by existing structures, and offered full scope to development along maximum advantageous lines.

What was probably the first power installation on the Manitoba reach of the Winnipeg river was undertaken some forty years ago at Pine Falls. The river as a whole does not lend itself to small developments, and it is only by taking advantage of particular local opportunities that such developments are even feasible.

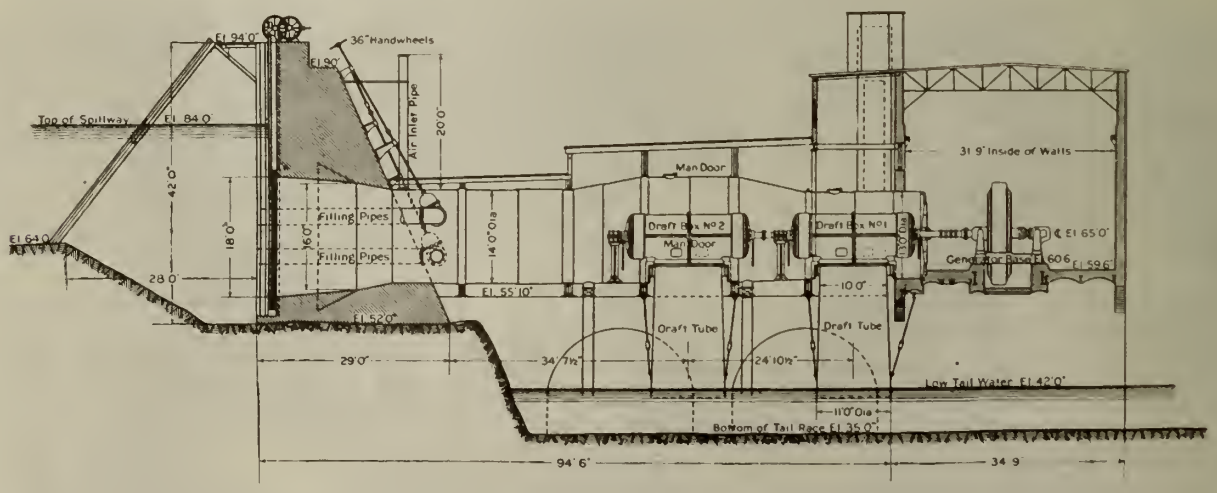


SECTIONAL PLAN

Scale of feet

At Pine Falls advantage was taken of the rock and shore formation on the left river bank to blast a power raceway for the purpose of carrying the head water level to a lumber and shingle mill located some 900 feet below. A head of about 9 feet was available. No diversion dam was constructed in connection with the head-race, the natural shore line providing of itself all the facilities which were necessary in this direction. The first large hydro-electric development constructed in Manitoba was that undertaken by the Winnipeg General Power Company on the Winnipeg River. The Winnipeg Electric Railway Company was incorporated a decade ago and amalgamated the interests of the Winnipeg General Power Company with those of the Winnipeg Electric Street Railway Company. This latter company operated the street railway system of Winnipeg, and also distributed power for domestic and industrial use, supplying the same from a steam station located in the city.

The site selected for the construction of the plant is located on the Pinawa Channel about 59 miles in a direct line from the city of Winnipeg. The general scheme proposed called for the diversion into the Pinawa Channel of a portion of the Winnipeg River flow, by means of diversion weirs across the main channel, and the concentration and development of a 40-foot head. The site of the power station is 7 miles distant from the village of Lac du Bonnet, which at the time of construction gave the nearest railway connection. The city of Winnipeg tramway line now runs within 4 miles of the station. The construction of the plant required the installation of a ferry at Lac du Bonnet, where the river is somewhat less than a mile in width, and the construction of a traffic road.



TYPICAL SECTION OF INTAKE DAM, PENSTOCK & POWER HOUSE

There are three diversion weirs which cross the main and secondary channels of the Winnipeg River at the head of the Pinawa channel. The main weir consists of a 1,379-foot concrete capped, rock-fill structure, with crest at elevation 105.5 company's datum, or 897.44 water power survey datum, connected with the river banks on either side by concrete spillways with crests at 879.44, bringing the total length of the main weir up to 1,652 feet. This

rock-fill section is not entirely water-tight, but fulfills the purpose for which it was constructed, that is, raising the water level above to a sufficient elevation to divert the necessary flow down the Pinawa.

There are two secondary weirs, one of timber, length 120 feet, crest at 896.94 and the other concrete, length 535, crest at 995.94, spanning two secondary channels, complete the diversion system. The discharge down the Pinawa to the plant is governed by a control dam, consisting of eighteen 9-foot and one 13½-foot stoplog sluiceways, with sills at elevation 881.94. Above the control dam and the diversion weirs there is a pondage area of approximately 5,800 acres, extending up stream to the foot of Slave falls.

The head-race from the control dam to the power station pond some 2½ miles below follows a somewhat winding route, which in places has been extensively improved, widened and straightened by excavation. The current is rapid, and the water surface, which above the weirs varies from elevation 898 to 901, drops to elevation 881 in the pond above the power dam. The tail-race presents conditions largely similar to those in the head-race, and the water finally rejoins the main river in Lac du Bonnet, about 13 miles below the station.

The power station is located on the west bank of the channel. The power house is 330 feet in length, 32 feet in width and 29 feet 9 inches from generator floor to top of roof truss. The generator floor is at elevation 851.44, with the bottom of the tail-race at 826.94. The intake dam is placed 95 feet upstream from the upstream

DOWNSTREAM SIDE OF POWER HOUSE AND TAIL RACE.

side of the power station, the water being led to the turbines through 14-foot steel penstocks housed for protection against frost, and with their entrances guarded by the customary gates and racks. The transformer house lies to the north, and is an extension of the power house, having a length of 176 feet, width 53 feet, height 36 feet 9 inches. The entire building is of fireproof construction, being built of brick and structural steel throughout.

The water power equipment consists of nine main units, four 2,595 h.p. and five of 4,788 h.p., and each unit consists of four horizontal inward-flow runners mounted in pairs and located longitudinally in the penstocks. The draught tubes drop vertically into the tail-race, with the water seal at elevation 832.69. The tubes are direct connected to the generators, and are equipped with Lombard governors. The electrical installation consists of four 1,000 k.w. and five 2,000 k.w. revolving field, 60-cycle, 2,300-volt, three-phase generators. The smallest machines run at 200 and the larger at 180 revolutions per minute. The generators are guaranteed to operate at full load at 95.5 per cent. efficiency. Excitation is provided by two 100 k.w., 125-volt, direct-current machines coupled to two 200 horsepower McCormick turbines, and operating at 600 revolutions per minute; and by two 175 k.w. 125-volt exciters coupled to three-phase 2,300-volt induction motors, operating at 514 revolutions per minute.

There are fifteen transformers provided which raise the voltage to 60,000 for transmission to Winnipeg. The Winnipeg Electric Railway also is provided with both

DAM DURING WINTER WEATHER.

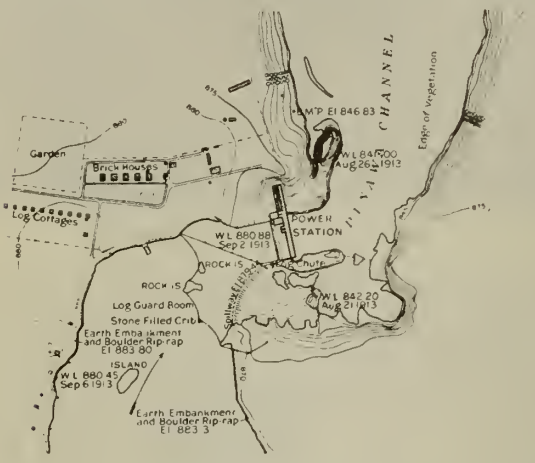
steam and storage battery plants operated in conjunction with the Pinawa station. When hydro-electric power was first used in Winnipeg, all electric light and power was supplied from a steam plant on Assiniboine Avenue, in Winnipeg, owned by the Winnipeg Electric Street Railway Company. This plant had a capacity of about 5,000 brake horsepower. Later the capacity of the Assiniboine Avenue power house was increased by 1,000 horsepower and an auxiliary steam plant of 12,000 horsepower capacity was constructed at Mill Street adjoining the company's main substation. Then the company built a storage battery house adjoining the Mill Street substation, and installed a 5,000 ampere hour storage battery, and the Mill Street station is now capable of producing 16,000 horsepower, and the Assiniboine Avenue plant approximately 60,000 horsepower and at certain seasons of the year all of the steam power and the storage battery plant is in use and operated to capacity.

Chief Engineer Johnston places the total power available for distribution in the city in the neighborhood of 45,000 horsepower. A free spillway, curved in plan, and 429 feet in length, with crest at elevation 879.44 crosses the old river bed along what was previously the crest of a natural fall, and connects with the left bank. Low earth embankments with top at elevation 883 are located on either bank. All headworks are constructed to withstand a pond level of 882. The head available for power purposes varies considerably, depending on the season and the flow in the channel. The original crest of the spillway was at elevation 875.67 and this was raised to its present elevation, 879.51, by the placing of tiers of timbers along

POWER DAM FROM HEADWORKS.

the crest while the average head available at the plant is 39 feet.

Regarding the transmission of this power it may be stated that the entire output of the station is transmitted to Winnipeg at 60,000 volts, over a 65-mile duplicate line which is supported on standard steel towers, 40 feet high and placed at 500-foot intervals. It crosses the main Winnipeg River with a span of 760 feet, on 72-foot towers, and the Red River with a span of 1,100 feet on 105-foot towers. The power is delivered to substations and distributed in the cities of Winnipeg and St. Boniface, the towns of Transcona, Stony Mountain,



GENERAL LAYOUT

Scale of feet

and Stonewall, and a dozen rural municipalities and also is supplied in bulk to the West Selkirk municipal plant.

On account of the fact that with a properly-controlled run-off the surplus flow passing over the diversion weirs and down the main channel can be profitably developed on the Seven Sisters reach, a study of the flow in the Pinawa is necessary to properly operate the plan, and also of the actual flow conditions since the plant was placed in operation is of considerable importance. As a result of the adverse ice conditions which occur during the winter season, and which produce sudden and considerable changes in the flow, and also from the fact that, until recently, no continuous systematic effort was made to secure a full record of the discharge, a determination of past conditions of flow at all seasons is a matter of considerable difficulty.

There has been a metering station established by the field staff of the Dominion Water Power Branch immediately below the control dam, and continuous records have been secured. This, combined with the existing gauge records provides a fairly accurate rating for summer conditions. In order to secure winter flow information it was necessary to rate the plant and to carefully study and utilize the load records. While the final collation and reduction of the results secured is not yet completed, sufficient has been accomplished to indicate that the 8,000 cubic feet per second which has been utilized throughout this report as the flow necessary to properly operate the plant is amply sufficient for the requirements of the present installation. The discharge frequently exceeds 8,000 cubic feet per second and there is generally a considerable automatic discharge over the free spillway.

Water Softening By Chemical Means

By Treating the Water Before It Enters the Boiler.—The removal of scale-forming components from water by chemical means, whether before or after entering the boiler, is accomplished by converting the calcium and magnesium compounds into practically insoluble forms, causing them to separate from the water and allowing the material to be removed by blowing down, filtering or sometimes by settling. Lime and soda ash are generally used for this purpose when the softening occurs before the water enters the boiler. The lime combines with the carbon dioxide which held the calcium and magnesium carbonates in solution. These are no longer soluble in the water after removing the carbon monoxide, and therefore separate from it. In a similar way the sulphate scale is removed by its conversion to insoluble carbonate by the soda ash.

The Lime-Soda Process.—There are in current use in power plants practically only one lime-soda process, of which there are two varieties, differing chiefly in the temperature of the water when treated. In all essential respects the two varieties are similar. The treatment consists of adding to the "raw" water softening agents in carefully controlled amount, which must agree with the composition of the water, mixing these thoroughly within the water, and permitting sufficient time to elapse for the separation of the "sludge" before the water is fed to the boiler.

In the case of the "hot-continuous" process, this separation is effected more rapidly, which permits of less storage capacity than in the case of in the cold-continuous. In all cases, though, it is of the utmost importance to provide sufficient storage space to allow the sludge to be completely deposited before the water is fed to the boiler: otherwise the partially completed softening process will be completed within the heater, and the purpose of the treatment will be largely defeated. Another advantage of the hot process is that it expels the air from the water and so reduces the corrosion.

The Zeolite Process.—This is entirely unlike the processes described above, and, unlike them, gives a water of from the softener and replaces it by the calcium and magnesium which had caused the hardness of the water. The hard water simply flows over the permutit packed in a cylinder or is forced up through it and flows from it with all scale-forming material removed. After a time the softener must be regenerated by allowing a solution of salt to flow over it, restoring its original composition and activity. The "Permutit" process is a well-known efficient variety of the zeolite treatment.

Advantages and Disadvantages of Zeolite Process

The construction and operation of this softening equipment is extremely simple, and, as already stated, water of zero hardness is furnished. On the other hand, in the case

GENERAL KEY PLAN

Scale of miles

of water to a high degree of temporary or carbonate hardness there is a correspondingly large amount of sodium salts introduced into the water, so that foaming is liable to occur (as is liable to occur when softening water of a similar composition by means of boiler compounds). In such cases the following modified form of the zeolite process is used.

The Lime Zeolite Process

In this an intermittent or continuous tank equipment, as described already under the lime-soda processes, is connected through a filter to a zeolite softener. Only lime is used in the tank, the soda compound being secured from the zeolite. The filter is placed between the tank and the zeolite softener to avoid any sludge coating the permutit particles and so impair its efficiency.

The Strength of Screws, Bolts and Nuts

In His Memorandum to the Manchester Steam Users' Association the Author Gives Some Interesting Data Regarding These Much Discussed Items of Mechanical Design

By C. E. STROMEYER

In my last year's Memorandum I mentioned that this subject was receiving consideration, but, with the exception of the few failures which have occurred in the meantime, no practical enquiry into this subject had been carried out. The subject was dealt with in a paper read at the Spring Meeting of the Institution of Naval Architects. It was there shown that very slight irregularities in the shapes of screw threads, and more particularly in the relative pitches of screwed bolts and nuts, could produce very serious local stresses at the roots of the threads, stresses which were found to be far more intense than the overall tension stresses in the core of the bolt. It was also found that the finer the threads the intenser the local stresses, and that, contrary to the generally accepted view, a bolt with a fine thread and, therefore, with a relatively large core is no stronger than a bolt with a coarse thread. In fact, this conclusion is almost self-evident, if, as an extreme case, we look on the bolt head as being a nut with microscopically fine threads welded together in order that they may not become disengaged. Of course the corner between the bolt and the imaginary nut would be a mathematically sharp one, and, as is well known, a sharp corner is very weak because, as would happen if a microscopic thread had actually been used, all the shearing stress is concentrated close to the corner. It follows that a bolt with a microscopically fine thread is a very weak structure. The other extreme case is a bolt with such deep threads that it has no core, a mere cork-screw. Such a bolt would also have very little strength; but there is some intermediate ratio of depth of thread to diameter of bolt for which the strength is a maximum.

Unfortunately, this maximum has a comparatively low value, being about one-third of the strength of the shank of the bolt measured over the threads. This, no doubt, accounts for the comparatively low stresses which are allowed in bolts. For instance, the permissible stresses on boiler shell plates between the rivet holes reaches 13 000 lbs. per square inch, and still leaves an ample margin of safety, whereas 10,000 lbs. on the cores of bolts, or about 7,500 on the shank of a bolt is considered fairly high. In reality the local stresses at the roots of the threads, combined with the longitudinal pull of 10,000 in the core, works out at about 20,000 lbs. per square inch, and it is probably only due to bolt materials being very plastic, and the threads being very small structures and, therefore, capable of adjusting themselves, that nominal stresses of 10,000 lbs. corresponding to actual local stresses of 20,000 lbs. do not result in failures.

These local stresses can be greatly intensified by making the pitch of the nut finer than that of the bolt and this malpractice is a not uncommon one. Most bolts have their threads cut with dies, and when these get blunt they tend to lengthen the bolts while they are cutting and compressing them. Then also large bolts and nuts are turned in lathes, and when these have seen much service, the leading screw has become more severely worn near the headstock where the nut would be turned than further off where the bolt thread would be turned. The result seems to be that many large nuts have finer threads than their bolts. The result is that when these bolts are loaded, it is only the threads near the lower end of the nuts which carry the load, and the severe resulting local stresses combining with the longitudinal pull, which is also a maximum at this level, produce very severe stresses; so intense indeed that no simpler means for breaking off a bolt end could be devised than using a hard steel nut with a relatively fine thread and wrenching off the bolt end.

Conversely a very marked reduction in the stresses near the lower level of the nut can be effected by making the nut thread of a slightly coarser pitch, say one-tenth per cent., than that of the bolt. When the nut is screwed on and a pull applied, the bolt will at first rest only on the upper threads of the nut, and gradually, as the load is increased, the bolt lengthens and more and more threads become engaged until all the threads are offering a fair share of resistance. It is of course no easy matter to produce absolutely correct pitches, but seeing that irregularities do occur, and that relatively fine threads in the nuts are dangerous, it would be an advantage to aim at not allowing the bolt thread pitch to exceed a certain limit, and also not allowing the nut thread pitch to fall below this limit.

Some insight into the nature of the stresses which occur in bolts and nuts is afforded by the following short modified extract from the paper previously referred to.

The depths of the nuts are assumed to be equal to the cores of the bolt. The numbers in the table, express the resulting stresses at the roots of the threads in the bolts in pounds per square inch for every 10,000 lbs. stress in the unreduced shank of the bolt.

No. of Threads per Core	Bolt and Nut Thread Pitches are equal		Nut Threads are 1-1000 coarser than Bolt Thread Pitches	
Diameter.	Bottom of Nut	Top of Nut	Bottom of Nut	Top of Nut
8	30,800	5,700	17,400	21,600
16	29,700	3,500	13,400	22,500
32	33,400	1,900	11,500	27,500

When the pitch of the nut thread is finer than that of the bolt, the maximum stresses at the roots of the threads are approximately given by the formula—

$$s = 4\sqrt{[T.Z.D. \div 2h \times (T \div 3E + 1/p)]}$$

where T is the tension in the core of the bolt of the diameter D. The depth of thread is h, E is the modulus of elasticity, say about 13,000 tons per square inch, and Z is the shearing modulus of elasticity of the threads, say 1,000 tons per square inch. The ratio of excess pitch of bolt thread over nut thread pitch is 1/p. The above formula does not apply unless 1/p is larger than 1-1000. For a tension stress T of 6.5 tons per square inch the value of T/3E is about 1/6000. We may therefore write—

$$s = 4\sqrt{[T.D. \div 2h \times (1/6 + 1000/p)]}$$

Let 2=65 tons, h/D=1-16 and p=1/1000, then s=31.2 tons per square inch, to which shearing stress a portion of the 6.5 ton tension stress has to be added.

If 1/p, the discrepancy between the pitches, should be 4/1000, which was actually the case with a boiler stay-bolt which failed, the shearing stress would be nearly 60 tons per square inch. No wonder, therefore, that this 2½ in. bolt should have failed while its nut was being screwed up.

Doubtless many similar cases occur in practice, but comparatively little notice is taken of them, they being attributed to bad material or carelessness on the part of the workmen. The faulty shape of the threads and pitches seems never to be suspected. However, as this subject deserves the very closest study, it is hoped that cases of broken bolts either of boilers or engines will be mentioned to me for the purpose of fuller investigation.

One reason why it is desirable to look very closely into this matter is the growing practice, started by American automatic tool makers, to supply mild steel which will mill easily. This steel con-

tains a large percentage of sulphur. Unfortunately phosphorus is frequently also present in large percentages, and then the bars are very brittle. Quite recently all the screwed stays of a new locomotive boiler had to be removed on account of their brittleness, and other loco boilers having screwed stays from the same steel-maker are constantly breaking their stays.

Drilling and Trepanning Tests of Various Qualities of Steel.

Letter	Relative Drilling Revolutions	Relative Trepanning Forces	Sulphur per cent.	Remarks.
O	0.96	1.21	0.010	Pure high carbon steel.
R	1.26	1.11	0.014	High phosphorus.
S	1.13	1.20	0.014	High phosphorus.
L	1.36	1.34	0.022	High phosphorus and nitrogen.
P	1.26	1.13	0.023	
N	1.26	1.06	0.026	
M	1.10	1.02	0.031	
BB	1.17	1.12	0.032	
W	1.09	1.00	0.034	
T	1.15	1.18	0.035	
Z	0.92	1.14	0.036	
J	1.13	1.00	0.043	High copper.
G	1.04	0.94	0.046	High copper.
V	1.02	0.98	0.047	
F	0.91	1.08	0.048	Very high phosphorus, also copper.
E	0.92	0.91	0.053	High phosphorus and copper.
K	1.01	1.01	0.056	High phosphorus.
B	1.07	0.78	0.057	
C	1.01	0.84	0.060	High carbon.
Q	1.04	1.04	0.060	High nitrogen and copper.
X	0.93	0.94	0.061	
H	0.94	0.79	0.062	High phosphorus and nitrogen.
A	1.07	0.92	0.078	High copper.
U	0.85	1.13	0.083	
D	0.71	0.89	0.193	Very high sulphur.
Y	1.06	0.05	0.031	High tenacity silicon steel.

The above-mentioned new stays contained 0.06 per cent. sulphur, 0.09 per cent. phosphorus, which is already rather high, and .020 per cent. nitrogen, which is very high and suggests that the steel maker had been using a large percentage of Bessemer scrap.

Some time ago, Mr. Dempster-Smith of the Manchester Municipal College, kindly carried out some drilling and trepanning experiments on samples of steel plates of which the chemical analyses and other tests will be found in my pervious notices. As there was a marked blunting of the tools after drilling or trepanning a few holes, a standard sample of steel was drilled for comparison both before and after drilling two test piece holes.

In table 11. the first column contains the distinguishing letter of the sample. The second one contains the relative number of revolutions of the drill per inch of depth of hole drilled, the load on the drill being constant. The third column contains the relative turning force for enlarging the drilled holes to a given size by trepanning, the rate of feed being constant. The fourth column contains the percentage of sulphur, and the fifth one contains remarks about the other impurities.

It will be noticed that sample L with only 0.022 per cent. sulphur offered a maximum resistance of 1.34. Sample D with 0.193 per cent. offered a minimum resistance of 0.71 and 0.89, say 0.8 mean. In other words, the increased percentage of 0.171 per cent. sulphur reduced the cutting resistance by 40 per cent. In view of this very great machining advantage offered by sulphur steels, efforts should be made to make them more reliable than they are at present. They seem to have been tried for motor chains, because blanks made from them punched very easily, but the experiment is said to have proved a failure.

Rules For Measuring Heating Surface of Boilers

The true heating surface of a tube is the side exposed to the hot gases, the inner surface in a fire tube boiler, and the outer surface in a water tube boiler.

Take All Dimensions in Inches

Rule for finding the heating surface of vertical tubular boilers: Multiply the circumference of the fire-box by its height above the mud-ring. Multiply the combined circumferences of all the tubes by their length, and to the sum of these two products add the area of the lower sheet. From this sum subtract the cross-sectional area of all the tubes and divide the result by 144; the resulting figures are the number of square feet of heating surface.

Rule for finding the heating surface of horizontal tubular boilers: Multiply one-half or two-thirds of the circumference of the boiler shell (depending on the amount of boiler surface that is exposed to the hot gases) by its length. Multiply the combined circumference of all the tubes by their length. Add these two products and divide the sum by 144; the resulting figures are the number of square feet of heating surface.

To find the square feet of heating surface in a tube, multiply the circumference of the tube by its length in inches, then divide by 144.

To find the circumference of the fire-box, tube, tube sheet or boiler shell, take the diameter of the tube, fire-box, tube sheet or boiler shell, that is, whichever it happens to be you want the circumference of, and multiply it by 3.1416.

To find the area of the fire-box, tube, tube sheet or boiler shell, take the diameter of the tube, fire-box, tube sheet, or boiler shell, that is, whichever it happens to be you want the area of, and square it (that is, multiply the diameter by itself). For instance, if the diameter of a tube is 3 inches, to square it you would multiply it by itself, 3, which would equal 9 inches, and then multiply the square of the diameter by 0.7854.

It is a general practice among manufacturers to rate boilers on the basis of 10 sq. ft. of heating surface per horsepower for water tube boilers and fire tube boilers and 7½ sq. ft. of surface for Scotch Marine boilers. These heating surfaces as specified are considered capable, under normal operating conditions. of evaporating 34.5 lbs. of water per hour from and at 212 degrees. However, this does not mean that this is the limit of the amount of water that this amount of heating surface will evaporate.

When the boiler is rated at a stated horsepower it is not to be understood that the boiler is in any state of strain when developing more than its rated capacity, that is, the horsepower. Broadly stated, the evaporating capacity of a certain amount of heating surface in a well designed boiler, that it is capable of producing, is limited only by the amount of fuel that can be burned under the boiler.

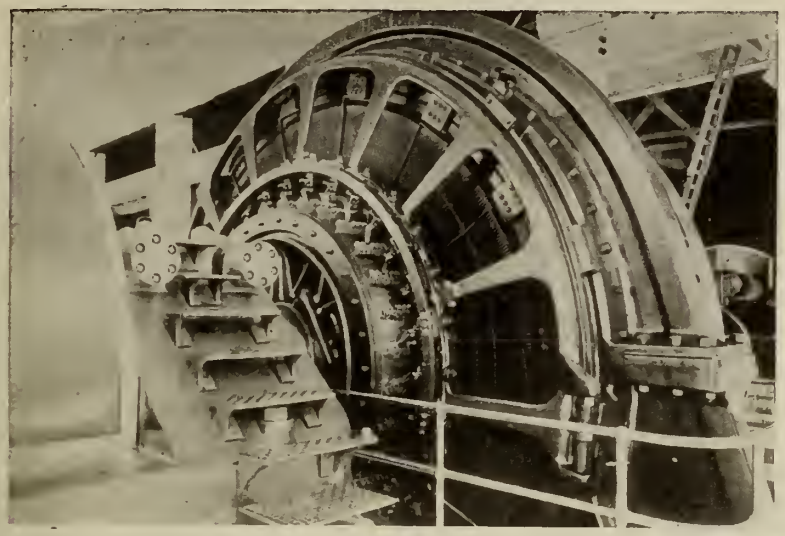
While this statement tends to lead you to believe that the question of capacity that can be secured in a boiler is simply one of making an arrangement by which sufficient fuel could be burned under a definite amount of heating surface to generate the required amount of steam. there are certain limiting features, structural and otherwise, in a boiler to be taken into consideration against the advantage of high capacity developed from a small heating surface.

The maximum capacity of a boiler expressed in boiler horsepower is given in terms of per cent. above the manufacturer's rated horsepower (by manufacturer's rated horsepower is meant the horsepower that is given for the boiler in the manufacturer's catalog, or, the horsepower the manufacturer rated his boiler at, when he sold it).

That the aeroplane engine is not above ordinary humdrum work is shown by the fact that one has recently been installed in a London factory as a stand-by power unit. It burns gas instead of petrol and the cooling water is circulated through a common cast iron radiator. It is an eight-cylinder engine, surplus from the war, and at the aerial rate of living would develop 200 horsepower, but has been rated at 75 horsepower on earth to give it a reasonable length of life. The space occupied by the engine is only 8 ft. by 5 ft.. by 5 ft. high, while its weight is about 800 lbs.

* * *

An English scientist declares that insomnia may be cured by removing excess moisture from the lungs. To put his theory into practice, he has devised a small machine for supplying warm, dry, filtered air, which the patient then breathes through a nose tube secured to the head with tape. The process is said not to be uncomfortable.



The Making of Commutators

The First of Several Articles Descriptive of Commutators and Their Troubles. This Article Deals With Their Construction

By W. F. SUTHERLAND

ONE of the most important features of direct current machinery is the commutator. In some respects it may be looked upon as a necessary evil for no other part requires such care in design, for the securing of proper commutation, and no other part is so liable to give trouble. When properly designed and

FIG. 1—MICA AND COPPER ROUGH MILLED READY FOR ASSEMBLY.

cared for, however, the commutator need be given but little attention and functions very well.

Materials of Construction

In essentials, not including brushes and current collecting devices, there are but three parts to a commutator, the current-carrying bars, the insulation and the supporting rings or spider.

Somewhat at variance with popular belief copper, so universally used, is not altogether chosen for its electrical conductivity but also on account of its high heat conductivity. Occasionally the design of the bar is such that electrical conductivity becomes a requirement demanding attention but in the great majority of cases if the requirements imposed by adequate heat conductivity are met with, electrical conducitvity becomes of secondary importance.

High speed machinery and the offsetting of wear as well as the securing of a uniform quality necessitate in most cases the use of rolled or drawn copper in place of castings for bars. A high elastic limit is especially desirable in view of recent advances in high speed commutator work for turbo-blowers, direct current turbo-generators, etc. In order to obtain a high elastic limit hard-drawn copper is used and for the most extreme requirements the hard-drawn copper is put through several subsequent rolling operations. Hard-drawn copper commutator bars should never be exposed to such temperatures as will anneal the copper. Temperatures above 250° C. seriously affect the elastic limit of copper, while at temperatures above 400° C. the elastic limit is greatly reduced.

Since a commutator is built up of many bars of copper it is necessary that these bars be made very accurately to gauge not only at both the thicker and thinner drawn edges but also in the centre. A difference at either of the edges will result in the bars building up into a commutator either larger or smaller in diameter. Differences in size at the centre of the width of the bar

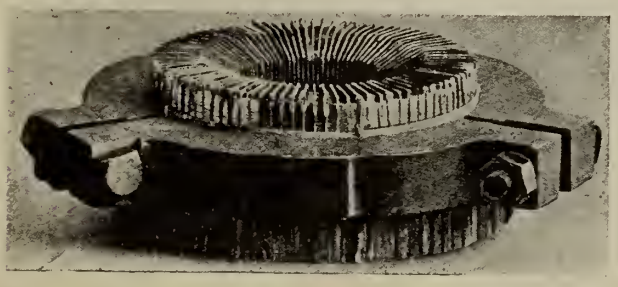


FIG. 2—COMUTATOR ASSEMBLED READY FOR BORING OUT.

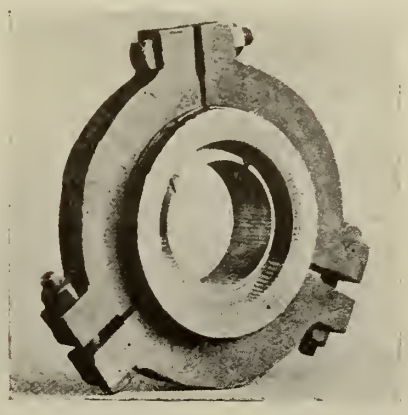

FIG. 3—COMMUTATOR FINISHED, BORED AND ENDS FACED.

arise in the process of drawing. The central part of the bar draws more readily than the edges and the cross-section of the bar, therefore, becomes instead of a wedge with straight sides, a wedge with concave sides.

Insulation

Various materials have been used in commutator construction but in all cases, in commutators of any size, mica is universally used. Fibre and molded insulation are used quite extensively in commutators of smaller sizes. Mica is perhaps the only material which combines the qualities of electrical resistance, equal wear with copper

and resistance to heat in a degree satisfactory to the manufacturer of direct current apparatus.

High mica has been the source of much trouble in the past and to-day is frequently the cause of faulty operation. Many micas are entirely unsuited for commutator construction and the only two which have been

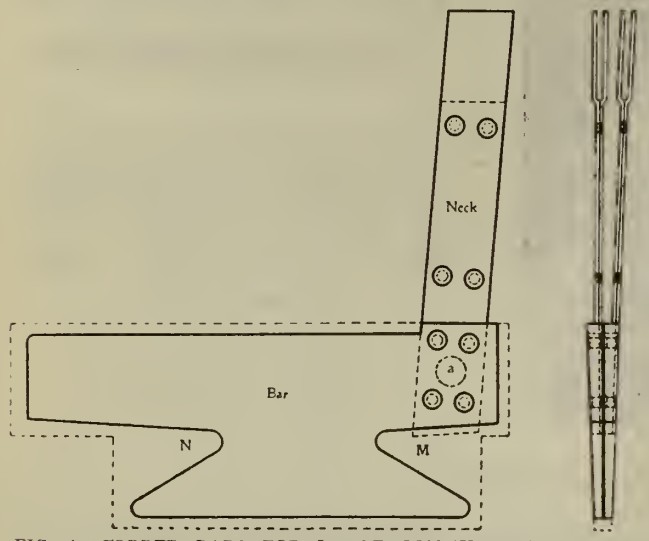

FIG. 4.—COPPER BARS FOR LARGE COMMUTATOR. THE DOTTED LINES INDICATE ORIGINAL SHAPE BEFORE BEING TURNED.

found to give uniformly good results are the Green Ceylon and the Canadian amber mica.

In the manufacture of commutator strips or insulation the naural mica is split up into five flakes and is united under pressure into a sheet of uniform thickness by means of a band, shellac in many cases. One-thirty-second of an inch is about the usual thickness for this strip material.

The bonding material used in built-up communtator mica must not be used in excess or some of it will be exuded in building up the communtator when it is baked. This baking process, as it is commonly termed, is not made either to get rid of moisture or an excess of bonding material in the insulation, but only serves to adjust the mica strips to the inequalities in the copper. If this is not done in the process of manufacture adjustment will take place when the machine is placed in service and loose bars may result, or at least, the commutator will need tightening up.

The vee ring or the insulation on the ends of the commutation bars is built up from mica in much the same manner as the strip insulation and this also needs to be heated when in final position.

The principle of adjustment of built-up mica to inequalities in the metal surface depends on the fact that when the bond is sufficiently softened, built-up mica will flow under pressure. The temperature usually reached in this baking process is about 125° to 150° C. for a shellac bond.

Mechanical Details

The supporting members which carry the commutator bars are usually made of cast iron, cast steel in the larger sizes, or brass in the smaller sizes where economy of space is of importance. Steel forgings are also used by some firms and make a very strong construction. Care is usually exercised by the manufacturers to see that sound material is used.

Building

The copper bar used for the segments is cut approximately to length and the rough bars are milled nearly to the size they will have in the finished commutator. The mica strip is also milled or otherwise cut roughly to size but is made slightly larger than the copper bars. In medium sizes before the commutator is built up a copper bar or neck is brazed to each segment for connection purposes, but in the smallest sizes and in most railway motors, where the neck is short, the segment and neck are in one piece, the mica strip extending to the top of the neck.

FIG. 6—MICA INSULATION FOR COMMUTATORS AND SHOWING THE VARIOUS STEPS IN MAKING A VEE RING
Photo Courtesy the General Electric Co.

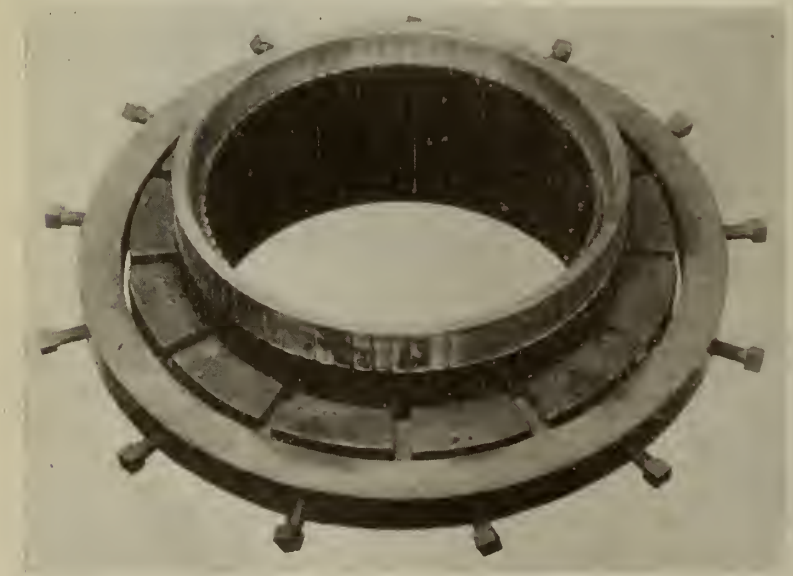

FIG. 5—COMMUTATOR IN RING, PARTIALLY TURNED. NOTE THE ARRANGEMENT OF THE BLOCKS AND SET SCREWS.
Photo Courtesy the General Electric Co.

In large commutators drop-forged copper bars are used. Fig. 4 shows a commutator segment for a large machine. The method of joining the bar and neck is shown clearly. This neck consists of two strips of copper fastened together with rivets and also securely riveted to the bar with countersunk rivets. Afterwards the neck and bar are brazed together and the whole finished off smooth. The dotted lines in this illustration represent the original form of the bar before turning.

The commutator is built up by placing the segments on end, side by side in the form of a circle with neck at the bottom and placing the mica strips between the copper segments. The clamp shown in Figs. 2 and 3 serves to tighten the assembly together, and after it is in place and drawn tightly home the commutator is baked in an oven, the clamping ring being tightened from time to time.

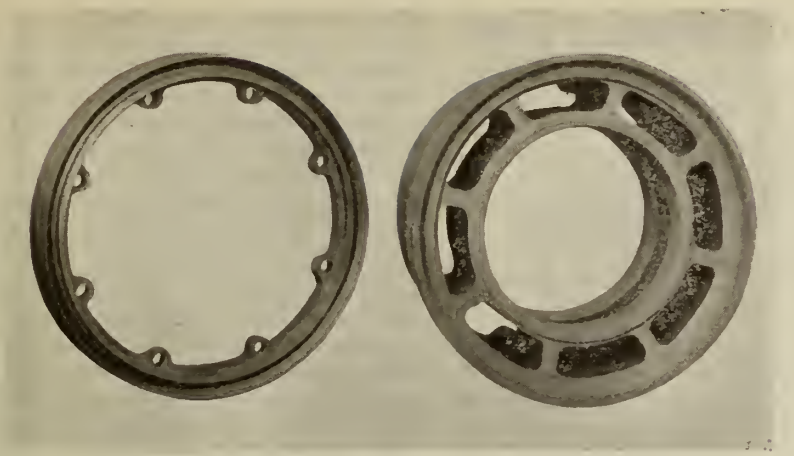

FIG. 7—COMMUTATOR SHELL AND CLAMP RING.
Photo Courtesy General Electric Co.

After the commutator is baked it is allowed to cool and is then machined as is shown in Fig. 3, the dovetails being cut and the inside surface trued up.

The iron or steel bushing is then placed in position with its insulating vee ring of mica and the steel vee or clamping ring also with its insulation placed in position. The whole assembly is then drawn up tight, the outer ring removed and the outer surface machined off.

In the building of larger commutators much the same practice is followed as for smaller ones. The commutator is built up on a circular horizontal surface plate. An iron block is clamped vertically on top the plate near the outer edge to act as a support for starting the row of bars. The copper segments are then set up side by side, with the necks at the bottom and projecting outwardly. A heavy movable block is used to keep the segments in an upright position while building. When the required number of segments have been built up to form a complete circle the whole is loosely bound with rope or tape and the mica sheets placed between the segments. When the commutator bars are very heavy and thick, the mica sheets must be built up with the bars. When the copper and mica are all in place binding rings are clamped about the bars to hold them together. Strips of fibre are used underneath the binding rings to protect the copper.

When the rings are adjusted in place they are supported upon wooden blocks and the mica and bars are evened up by driving against the fibre strips. The bars are set perpendicular by making the edges of the mica strips parallel to a straight edge set perpendicular to the surface plate.

When all the bars are properly set the screws in the clamping rings are tightened and the commutator is ready to be baked. In the baking process the commutator is placed upon a large iron block having a circular hole in the centre. The inner surface is lined with sheet iron to prevent the flame from carbonizing the shellac in the mica strips and heat is supplied by gas flames. During the baking the set screws in the binding rings are occasionally tightened and any excess shellac forced out. When the shellac is thoroughly dried out the commutator is then carried to a boring mill, where the inner surface is machined off. The mill is operated at a high rate of speed and air is sometimes used to blow the turnings from the work. Both ends are also faced off and the commutator tested for short circuits.

FIG. 8—LARGE COMMUTATOR IN PROCESS OF ASSEMBLY.

If one should be found it may be due to particles of copper making a connection between adjacent bars, in which case the connecting copper is cut away by a sharp tool; or it may happen that the trouble is in the mica below the surface. To remedy this it is necessary to remove sections of the clamping rings and to replace the faulty mica with new. After a thorough test the inner surface is sandpapered smooth and shellaced, after which the commutator is ready to be mounted upon its supporting spider. The outside surface is then machined off either when the armature is wound and connected up or, in the case of larger machines, separately in a boring mill.

It is estimated that there are between four and five million acres of land in the United Kingdom which might be planted with timber. Of this amount about one-fourth should be planted during the next forty years, according to the Forestry Bill, which has passed the second reading. This amount would put the country in a position to subsist without imports of timber for three years.

* * *

According to the "Iron and Coal Trades' Review," the Lens coal pits are flooded to the ground level, and at the lower level mines the water is flowing out over the ground, threatening flooding of the countryside. The Mining Society of Lens estimates that it will take eighteen months to pump out the water, and that the working of the coal in the higher seams cannot be resumed until the end of 1920. The complete restarting of the mines of Lens and Lievin will take at least ten years. The powerful pumps required have been on order for a considerable time. They will be operated electrically, from an electrical supply taken from the generating station at Harnes.

* * *

Sir Dugald Clerk, in a paper read before the North-east Coast Institution of Engineers and Shipbuilders, points out the well-known fact that the efficiency of the Diesel engine is largely due to the high compression ratio of 12 or 14, the compression ratio with the gas engine being usually seven, although the author states that "from the results of prolonged experience it may be taken that for explosion gas engines the extreme practicable compression ratio is 10 to 1, and the maximum probable brake thermal efficiency is 39 per cent.

* * *

The author remarks that there appears to be only one method open to increase the heat economy in an internal-combustion engine in a practical way, and that is by using regeneration of heat in some form. If in large installations the steam were used in a high-efficiency Parsons steam turbine, requiring 10 lb. of steam per b.h.p. hour, 25 per cent. could have been added by steam expansion to the brake power obtained by internal-combustion.

MICHIGAN had a dozen buggy factories ten years ago, but now only one. Gasoline is pushing the old gray mare off the map.

The Properties and Uses of Colloidal Fuel

NO problem in America during the recent war reached a more acute stage than that of maintaining a sufficient supply of fuel oil and petroleum derivatives, and among the various problems taken up for study by the Submarine Defence Association was that of securing a smokeless fuel—logically essential to effect concealment for a ship lying just below the horizon, but so often self-betraying because of the telltale trail from its funnel. In the various researches were included trials afloat of powdered coal. This fuel commended itself mainly because of the very complete combustion which could be secured, and exhaustive tests were made aboard the U.S.S. Gem. During preliminary trials attempts were made to burn the powdered coal by first firing oil in conjunction with pulverized coal through separate feeds, and from these tests spring the suggestion to combine fuel oil and powdered coal, so that they they might be fed simultaneously to the oil burners.

Being familiar with the oil industry and with the efforts previously made to evolve a colloidal fuel, and knowing of the availability of certain coals in Europe, where oil is scarce, Mr. Lincoln W. Bates, chairman of the Submarine Defence Association, turned his attention to devising coal-and-oil mixtures, because he believed that an oil-saving fuel could be reached in that way. The first results of trial combinations of coal and oil, made in the autumn of 1917, were instructive and gratifying, but they were not satisfying. Nevertheless, the investigation gave promise of practical use, although neither the oil nor the coal employed was then up to the United States Navy or the British Admiralty standards. A special search was next undertaken for the purpose of discovering a "fixateur" which would render the composite sufficiently stable when oil and coal up to official standards were employed. New supplies were obtained and diverse experiments were conducted with continually better results. After a six months' struggle and many trials, by December of 1917, it was found that certain chemical ingredients incorporated in the admixture created a molecular state wherein the coal content would not settle out at service temperatures. Three months later the work of the laboratory was so far successful that the time for demonstration had arrived.

Many oils are readily available in their natural state for mixing with coal to form a colloidal fuel, while others require slight transformations to effect this, but all varieties of coal are suitable for incorporating with oils. These include, besides the usual anthracite and bituminous coals, lignites and even peat. The low-grade European kinds may be used pulverized, when they could not be used advantageously as coal alone. The salient point is the B.Th.U. content. A coal so low in thermal units as to leave the B.Th.U. value of the colloidal composite much below that of oil alone might not be worth while, except under the extreme stress of a war-time emergency. Another important factor affecting the actual heating efficiency of coal-and-oil combinations is, of course, the amount of ash left on complete combustion.

In all practical coal-and-oil mixtures it is necessary to prepare the coal by pulverization, an art which has been largely developed within the past few years. It is now possible to pass more than 90 per cent. of the pulverized coal through a screen of 300-mesh, i.e., 90,000 holes per square inch. This fine subdivision enables the coal and oil to be stabilized when suitably treated. It has been established both ashore and afloat that "any solid fuel which, in a dry pulverized form, has two-thirds of its content combustible, is suitable for steam generating purposes." All coals may be pulverized. Also inferior grades such as anthracite culm, rice, dust and "slush," as well as bituminous and lignite slag, screenings, etc., can be burned in pulverized form. Coal cokes and crude oil coke, charcoal, and pulverized wood may be incorporated in colloidal fuel and give good results. To obtain satisfaction from these sources of carbon, however, they should be dried and milled so that the surface or free moisture will not exceed 1 per cent. It is reported authoritatively that: "The total cost for preparing pulverized coal properly in a suitably equipped drying and pulverizing plant will range from 15 to 45 cents a ton, depending upon the capacity of the plant."

Of course, the crux of a satisfactory colloidal fuel is stabilizing the coal in the oil. There are only four ways yet known to increase the stability of a coal-and-oil mixture. One is to subdivide the coal to such fineness that a chemical combination between coal and oil particles takes place. This would be a true colloidal mixture. Another way is to thicken the viscosity of the oil so that sedimentation of the coal powder is delayed. A third is to introduce "fillers" of light particles, which would act as nuclei for flocculation, but which by reason of their buoyancy would operate to reduce sedimentation. The products obtained by any of these alternatives are either too expensive or impracticable for storage, or are not acceptable for daily use. By means of a fourth method it is now possible to introduce into the mixture of oil and powdered coal a fixateur which produces a colloidal fluid having the desired properties. The fixateur which has been developed has in its mixture certain characteristics, readily obtainable, which prevent sedimentation for a long period of time. The nature of this fixateur cannot be disclosed at present. The fixateur need constitute but 1 per cent. of the composite—only 20 lb. in a ton, and no doubtful process or industrial problem is involved in its preparation.

With the character of a proper fixateur established after much research, mixtures of coal and oil so stabilized were tested in a practical way under rigorous condition aboard the U.S.S. Gem. For this purpose fuel oil complying with the specifications of the United States Navy was supplied, whilst of the coal 99.7 per cent. passed through a 100-mesh screen, 98 per cent. through a 200-mesh screen, and 85 per cent. through a 300-mesh screen. The calorific value was determined to be 13,974 B.Th.U. per pound. The calorific value of the mixture can be grasped from the accompanying table:

In the report upon this colloidal fuel it is stated: "The results obtained under standard conditions with the Parr calorimeter show that up to 30 per cent. coal replacement the composite has equal calorific value per unit volume. The composite used was not the most favorable possible; it had a higher fixateur content—2.5 per cent.—than is necessary for stabilizing, while the coal used was not of the highest grade available."

Fuel	Per pound, B.Th.U. fd.	S.G. fd. 25°/25°	Per unit, volume relative heat units
Heavy crude fuel oil	18,330	.900	16,497
Same oil and 20 p.c. soft coal without fixateur	17,307	.968	16,753
Same oil and 25 p.c. hard coal without fixateur	16,390	.995	16,308
Navy oil, No. 1	18,669	.924	17,297
Same oil and 30 p.c. coal with fixateur	17,023	1.035	17,619
Coal	13,974	....	.....

Regarding the spraying and atomizing of the colloidal fuel, numerous laboratory tests were made. The results are thus summed up: "While it is not possible to make on a small scale a satisfactory trial of the burning and heating properties of the fuel, it is possible to test its capacity for being sprayed and atomized. For this purpose it is sufficient to have a reservoir of the fluid connected to a compressed air line with gauge, and, on the other hand, to an oil burner or atomizer. For our experiments we used an air injector oil burner, with about ⅛ in. nozzle, regulated by a cone valve, and having a by-pass for injection of the atomizing air current. This air was supplied by a shunt from the main line, and provided with an independent pressure gauge. The fuel was heated to nearly 158 deg. Fah. in a reservoir, which corresponded to a preheater in an oil-burning installation. Quite effective spraying was obtained with a pressure of 70 lb. to 80 lb. on the reservoir and with from 20 lb. to 30 lb. in the air shunt."

At first sight, it might seem that a mixture of a fuel oil of ordinary B.Th.U. value with a coal of a lower B.Th.U. value per pound would make a composite having a reduced B.Th.U. value per unit of volume when compared with fuel oil alone. Such a result, however, is not the case if good grades of coal be used. Of course, there would be a deficiency in the colloidal fuel if coals of relatively low B.Th.U. value were employed. According to the findings of the Submarine Defence Association, we have this interesting fact: "Assuming a volume of 3 cubic feet of colloidal fuel, of which 2 cubic feet would be oil and 1 cubic foot pulverized coal. The fuel oil weighs approximately 58 lb. per cubic foot, and the heat value, for example, is estimated at 19,000 B.Th.U.'s per pound. Therefore 2 cubic feet will contain 2,204,000 B.Th.U.'s. One cubic foot of solid coal weighs approximately 80 lb., and, assuming an average B.Th.U. value of 14,500, one cu. ft. of coal would contain 1,160,000 B.Th.U.'s. Therefore a combination of the two fuels, oil and coal, and in the ratio of 2 of oil to 1 of coal, would contain 3,364,000 B.Th.U.'s, or 1,121,333 B.Th.U.'s per cubic foot, as compared with only 1,102,000 B.Th.U.'s per cubic foot of oil. The heating values will vary directly, according to the B.Th.U. value of the coal and the oil."

Pulverized coal in a dry state weighs only about 35 lb. to 38 lb. per cubic foot, according to the gravity of the coal and to the degree to which the coal has settled. There are, however, no voids in the coal when mixed with the oil, and hence it must be taken as a solid. Colloidal fuel can be made of a great many grades of coal and oil, rendering available in numerous cases fuels heretofore looked upon as undesirable. Colloidal fuel made with pressure-still residuals —such as oil, wax tailings, crude oil coke—is a success. From these residuals an ashless fuel is prepared so low in sulphur that it will command a premium because of its value in making high-grade alloy steel. The Submarine Defence Association, in response to the wish expressed by the Admiralty, extended its research to coal tars. It is possible to announce confidently that it is entirely practicable to blend petroleum oils and coal tars and so stabilize the mixture that the powdered coal, pulverized coke, and asphaltic substances will not be precipitated, but, instead, will produce a stable liquid fuel that can be shipped, piped, and stored. This means that countries without oil, like Australia, France, Italy, and England, may themselves produce quite half of the substances needful to the making of a satisfactory liquid fuel.

It has been found entirely practicable to hold suspended in oil for months running from 30 per cent. to 40 per cent. of coal. The average size of the coal particles is many times that of the graphite particles in lubricating compounds. It is possible to combine in a stable liquid fuel about 45 per cent. of oil, 20 per cent. of tar, and 35 per cent. of pulverized coal, thereby replacing more than one-half of the oil now used, while securing equal, if not greater, heat values per barrel, not to mention a considerable saving in cost.

Regarding the nature of the fixateurs and the process by which they are incorporated with the oil and coal, it will have to suffice at present to say that the fixateurs and treatments produce a state in which the settling force of gravity, operating upon the particles somewhat agreeably to Stoke's Law, is overcome by peptization, absorption, Brownian movement, electrical factors, and chemical and physical phenomena, including such as obtain in the case of colloids and metals. The exception, however, is that in the composite fuel many of the particles are above colloidal size.—"The Engineer."

SURFACE CONDENSING PLANT TEMPERATURES

When tuning up surface condensing plants it is highly desirable that, having a good vacuum, the hotwell water temperature should be kept as high as possible consistent with that vacuum, and a little trouble taken to regulate the cooling water supply to suit the load on the condensing plant will be amply repaid.

There should not be more than 10 deg. F. difference between the hotwell water temperature and the theoretical temperature:

Vacuum	Theoretical Temperature
20	161.28° Fahr.
21	166.83° Fahr.
22	151.97° Fahr.
23	146.55° Fahr.
24	140.42° Fahr.
25	133.32° Fahr.
26	124.89° Fahr.
27	114.34° Fahr.
28	100.05° Fahr.

A difference of more than 10 deg. F. indicate either (a) air leaks in exhaust main; (b) inefficient air pump; or (c) if vacuum is high too much cooling water passing. There should not be more than 18 deg. to 30 deg. F. difference between hotwell temperature and the cooling water discharge temperature. A high difference indicates either (a) an excess of cooling water, or (b) a dirty condenser. The former is shown by low hotwell temperature, the latter and more usual by high hotwell temperature. A low vacuum with a high temperature in both hotwell and circulating water discharge shows that insufficient circulating water is passing, and may be due to centrifugal pump running at wrong speed, or to its impeller being worn.

It should also be remembered that, although steam turbines require as high a vacuum as can be obtained, in order to obtain the best results as regards coal consumption, reciprocating engines generally give their best results with about 25.5 in. to 26 in. vacuum, the hotwell temperature being kept up as near as possible to the theoretical temperature.

INTERNATIONAL MACHINERY EXPOSITION ANNOUNCED

Announcement of the International Machinery Exposition to be held in Grand Central Palace, New York City, has been made by the Merchants' and Manufacturers' Exchange of New York. This is to be one of the most advanced steps made in the machinery industry since the war ended ,and will be a permanent affair. October 15th is scheduled as the opening date, at which time it is expected that hundreds of machines will be in actual operation on the floor. The exposition will occupy 50,000 square feet of floor space, in the high structure, which is the largest exposition building in the world and will include a most comprehensive display of modern engines, lathe milling machinery, planers, drills, screw cutters, presses, boring, can-making, wood-turning machines, etc. The Merchants' & Manufacturers' Exchange, which operates Grand Central Palace, is owned and controlled by the Nemours Trading Corporation, of which Alfred I. duPont is president. It has nineteen branches and 3,000 selling agencies throughout the world, and is one of the most remarkable organizations of the sort in existence. The Merchants' & Manufacturers' Exchange will operate eight permanent industrial expositions in the Palace on the eight upper floors of the 12-storey building. The four lower floors will be used for temperary exhibit, such as the annual automobile show, motor boat, flower show, etc.

Visitors at the Internationl Machinery Exposition will also find the other expositions in this building of considerable interest, included among them are the International Factory Appliance Exposition, International Mining Machinery Exposition, International Farm Tractor and Implement Exchange, and International Exposition of Mining Industries, etc. The advantages of this great world trade clearing house are obvious. Manufacturers will have their exhibits side by side, affording easy comparison. Interchange of ideas and the opportunity to observe what is new and improved in machinery, will be of decided benefit to all who are connected with the industry. Then, too, familiarity with the implements and machinery of one industry so often leads to appreciation of their applicability to another.

Lloyd L. Warfield is manager of the Machinery Exposition and will be assisted by an able staff. Fred W. Payne is general manager of the Merchants' & Manufacturers' Exchange, and has general supervision of all of the expositions. Inquiries should be addressed prior to Sept. 15th to Suite 421, 405 Lexington Ave., New York City, and after that date to Grand Central Palace.

Using Pulverized Coal as a Boiler Fuel

The Following Paper Read Before the Detroit Meeting of the A.S.M.E. Gives Some Interesting and Useful Data Relative to the Use of This Fuel

By N. C. HARRISON

THE peculiar conditions as they exist to-day, on account of the war and for other reasons, such as the gradual disappearance of sources of fuel, like natural gas, and the shortage in the supply of crude oils, which have become of too great value for ordinary fuel purposes, have compelled those interested to consider the possibility of the adoption of pulverized coal as a fuel, to replace their present methods of operation. Pulverized coal was first used in the United States about 26 years ago for the economical burning of the cement rock in the rotary kilns of the portland-cement industry.

Pulverized coal was first applied successfully for economical reasons in connection with the burning of portland cement. The growth of the portland-cement industry also had a great bearing on the development and use of pulverized coal, in that, it is in this industry that pulverizing machines were brought to the present high state of development, for in the manufacturing of cement in the neighborhood of 1,100 lbs. of raw materials, clinker and coal must be ground to produce one barrel of portland cement weighing 380 lbs. As there are a hundred million barrels of portland cement made in this country annually, these figures will give one a reason why pulverizing machines have been so highly developed during the last few years. Fine grinding of the raw material means reduction in the quantity of fuel required and also makes possible the highest quality of the finished product, so far as the chemical analysis or combination is concerned. Fine grinding of the clinker means increased strength for the reason that the hydraulically active units in cement are in direct proportion to the percentage of fine or impalpable powder in the finished product.

The application of this form of fuel has been gradually taken up by engineers connected with other industries, who have speedily recognized its value to such an extent that the steel industry to-day is using in the neighborhood of two million tons of pulverized coal annually in various types of furnaces such as open-hearth, heating, puddling, soaking pits, continuous-heating, reheating, annealing, forging furnaces, and furnaces of practically every description where heat is required.

The copper industry is using between one and two million tons per year in ore-roasting furnaces, reverberatory and copper-melting furnaces of all types. Large amounts of pulverized coal are used in rotary kilns (other than the cement industry) for the desulphurizing and roasting of various grades of ores; for nodulizing blast-furnace flue dust so as to make available products heretofore very expensive to recover; for burning lime to oxide of lime for use in open-hearth furnaces; for burning dolomite for open-hearth furnaces; and for the calcining (or driving off of CO_2 gas and water of crystallization) of various minerals, from which are obtainable such commodities as plaster of paris, stucco, potash, etc. A total of approximately ten million tons of pulverized coal are burned annually in the United States in the above industries.

A still further and very important development is now going on, which will, when it attains its growth, require more pulverized coal than probably all of the other industries combined, and that is in its application to locomotives, particularly in the West. This application is now being developed. There is still another field in which enormous quantities of this fuel will be used and a field in which we are all concerned, and that is in the generation of power in stationary power houses.

Practically any coal can be burned in pulverized form with a proper furnace and burning equipment. Each application, however, must necessarily be governed by the quantity of the fuel available in the district in which it is made. Generally speaking, however, the coals which would give the most satisfactory results would be those in which the ash content would be less than 10 per cent., the volatile averaging between 30 and 40 per cent. and the fixed carbon between 40 and 50 per cent. The sulphur content should be low, although coal with a sulphur content running as high as 4½ to 5 per cent. is being burned in pulverizing form under boilers without any detrimental results. The ash should have a high melting point. These statements, however, are tentative, as most excellent results have been obtained from all sorts of coals, differing widely from the ideal analysis stated.

It is very apparent that the development in this method of burning coal has brought coals, from which heretofore very inefficient results have been obtained, within reach of a great many consumers. For instance, from Texas to Edmonton, Alberta, the country is underlaid with various grades of lignites, low-grade mineral coals with high moisture content and of such a nature that the ash would melt or flow down on the grates, thereby preventing the highest efficiency from being obtained. They are of such a nature that their use in gas producers is not very satisfactory, so that until the development and burning of these coals in pulverized form was an assured success these coals were not used in as large quantities as is now possible. The largest deposits of lignite and mineral coals appear to be in the Northwest awaiting future development when proper means are at hand for obtaining the highest possible economy from their combustion, and the location of these large deposits will now be of great value to the districts in which they are located.

Around steel plants there are large quantities of waste fuel such as coke breeze. This fuel is being used to a certain extent on some forms of grates, with forced draft, but it can be burned in pulverized form under boilers for the generation of power, and possibly in the open-hearth furnaces for making steel. In the anthracite field there are large quantities of coal daily pumped back into the mines, which coal is a result of the washing and crushing operation, for bringing the coal to commercial sizes. I understand that eight to ten million tons annually of this silt are allowed to be pumped back into the mines to fill up old workings.

A number of the coal companies are now carefully investigating the application of pulverized anthracite or low volatile coals with a view to using this waste coal in pulverized form so as to obtain power for its use, making available coals of higher grade for the market, which they are firing at the present time. A very successful installation of this kind is in operation at Lykens, Pa.

The above statements have been of a rather general nature so as to bring out forcibly the fact that coal in pulverized form is going to become one of the most important fuels. The results thus far obtained have shown that with installations properly designed and installed, that from an operating standpoint it is not only a desirable fuel but one which will eventually become necessary on account of its economy.

What is Pulverized Coal?

The average man will tell you that pulverized coal is coal ground to a powder. Any coal which is ground or powdered from his point of view is pulverized coal. From a technical standpoint pulverized coal is that coal which is properly dried, crushed and pulverized so that the product contains the highest percentage of impalpable powder. Merely powdering coal does not fulfill the requirements. Coal must be pulverized so that at least 95 per cent. will pass through a 100-mesh sieve having 10,000 openings to the square inch, or in terms of dimension 95 per cent. must

be less than one two-hundredth of an inch cube.

The average person does not fully realize to what a high degree of fineness it is possible to reduce the coal today by pulverization. The finer the coal is pulverized the more efficiently it can be burned and the more readily it will be diffused when mixed with the air for combustion and fed into the furnaces. A cubic inch of coal pulverized so that 95 per cent. will pass through a 100-mesh sieve will contain over two hundred million particles, none of which will be greater than one one-hundredth of an inch cube, and a large percentage will be less than one six-hundredth of an inch cube. A cubic inch of coal has a superficial area of 6 sq. in., but the combined area of these multitudes of small articles shows that when the coal is ground to above mentioned degree of fineness the superficial area will increase to nearly 30 sq. ft. or an increase in area of approximately 700 times. This increase in area permits perfect and instantaneous combustion. Its rapidity depends directly upon the surface exposure. This is one of the reasons for the grinding.

Pulverizing certainly does not change the nature of the coal. We do, however, change the form of the coal to a certain extent in pulverizing it, in that we change it from a solid into a fuel having liquid properties. As the coal is pulverized it is mixed with air, and when handled in the conveyor it flows like water; when fed to the furnaces it is more or less like a gas, and the furnaces must be designed to burn a gaseous mixture.

Description of a Coal-Pulverizing Plant

A pulverizing plant consists of three main units: a crusher, a crushed-coal drier and a pulverizer. The number of each one of these three main units will depend on the size of the plant. The coal is dumped in a track hopper and conveyed by either a belt or apron conveyor into hopper, feeding single-roll coal crusher, or where slack coal is at hand, direct to elevator pit. After being crushed to about one inch in diameter, it passes by gravity to elevator pit, where it is taken by bucket elevators to the drier storage bin. Automatic weighing scales may be installed if desired before the drier storage bin. Magnetic-separator pulleys are also installed, where a belt conveyor is used from the track hopper to remove iron or steel scrap in the shape of nuts, bolts, pick-points, wedges and such foreign matter, which would interfere with the pulverization.

From the drier storage bin the coal passes to a coal drier. This drier must be of a size to deliver the required quantity continuously, thoroughly dried. The drier is heated either by hand-firing on grates, or by pulverized coal, so arranged in either case to avoid igniting the drying coal. The cylinder of the drier is rotated by power, either a small motor or line shaft being used. The dried coal falls from the drier through a chute into the pit of an elevator. In this chute the coal passes over another magnetic separator to remove any final pieces of metal which might be left in the coal and which were not caught on the magnetic separator spoken of above.

This elevator carries it to a storage bin set aloft for supplying the pulverizer. By spouts and gates the coal is permitted to enter the pulverizer as desired. This pulverizer grinds the coal to the fineness required. From the pulverizer the coal is conveyed in various ways to the pulverized-coal bins. With the type of mill used at our plant, it is carried by spouts from the mill to the pit of an elevator, which carries it aloft to the screw conveyor, which feeds the pulverized-coal bins. In another type of mill the fine pulverized coal is conveyed by suction fan from the mill to a cyclone separator, properly located over the pulverized-coal storage bins, or over the screw conveyor to the pulverized-coal storage bin. This separator will allow the coarser particles to fall back to the mill, to be reground, while the fine dust passes to the storage bin. No fine-dust elevator is necessary with this mill.

These pulverized-coal storage bins are of a capacity proportional to the service and hold a supply in excess of the amount required in the intervals when the grinding is not going on. Thus the mills may supply in eight to ten hours all that the furnaces may use in 24 hours, by making provision therefor.

If the pulverizing plant is located within 200 ft. of the furnaces and the furnaces are of large capacity, these storage bins are located directly at the furnaces. But if there are numerous small furnaces located at a considerable distance from the pulverizing plant, we then locate the above storage bins at some central point and convey from these points to the various furnaces by means of one of three methods: first, screw conveyor; second, in a mass by means of compressed air; third, in suspension in a current of air. We now have the pulverized coal at the furnaces ready for use.

Costs of Pulverizing Coal

The cost of the operation of pulverizing coal depends upon four items: first, the amount of moisture that must be expelled from the coal before pulverizing; second, the cost of labor; third, the cost of coal delivered at the pulverizing plant; fourth, the cost of electricity. Table 1, issued by a pulverized-coal engineering company, gives the cost of pulverizing plants, including buildings, and costs of pulverizing coal in plants of capacity from 10 to 250 tons per day. These figures include all costs, except interest and depreciation, in the pulverizing plant proper, and deliver the dust from the top of the last elevator to the screw conveyor, which feeds the pulverized-coal storage bins.

TABLE 1. COSTS OF COAL-PULVERIZING PLANTS AND COSTS OF PULVERIZING COAL PER TON NET.

Tons daily	Total cost pulverizing per ton, dollars.	Cost of plant including building, dollars	Labor, hours	Labor, cost per ton, dollars
10	0.56	31,000	10	0.30
20	0.51	31,000	20	0.25
30	0.49	31,000	30	0.23
40	0.49	31,000	40	0.23
50	0.39	37,000	26	0.13
60	0.39	37,000	30	0.13
70	0.39	37,000	40	0.13
80	0.39	37,000	40	0.13
90	0.39	37,000	46	0.13
100	0.34	45,000	34	0.09
110	0.34	45,000	37	0.09
120	0.33	45,000	40	0.08
130	0.33	45,000	44	0.08
140	0.32	50,000	45	0.06
150	0.32	50,000	47	0.06
160	0.32	50,000	50	0.06
170	0.32	50,000	54	0.06
180	0.32	50,000	57	0.06
190	0.30	62,000	48	0.04
200	0.30	62,000	51	0.04
210	0.30	62,000	53	0.04
220	0.30	62,000	56	0.04
230	0.30	62,000	59	0.04
240	0.30	62,000	61	0.04
250	0.30	62,000	63	0.04

Data on which Table 1 is based.

Labor rate: Millers, 30 cents per hr.; drier firemen, 20 cents per hr.; common labor, 20 cents.

Cost of drier fuel: 6 cents per net ton, based on 7 per cent. moisture. Coal at $5 per ton delivered.

Evaporation: 6 lb. per lb. of coal burned or 26 lb. of coal per ton.

Repairs: 7 cents per net ton. This includes whole pulverizing plant, all machinery.

Power has been based on 12.7 cents per ton pulverized, and a consumption of 17 h.p.-hr. per ton pulverized at 1 cent per kw.-hr. or about $54 per h.p. per annum.

We have taken from Table 1 figures relating to those plants having daily capacities approximately the same as our plant, and by changing labor rates to correspond to our rates have recomputed these figures as given in Table 2.

Table 3 shows actual costs at our plant, and these are slightly higher than figures given in Table 2.

Open-Hearth and Metallurgical Furnaces

The development and use of pulverized coal in this country has been primarily due to its application in the cement industry and its gradual application to other types of metallurgical furnaces. Marked economies, and in some cases increased production, have been obtained from this fuel and within the last few years it has been applied very

TABLE 2 COSTS OF PULVERIZED COAL PER TON NET.

Tons daily	Total cost pulverizing per ton, dollars	Labour hours	Labor, cost per ton dollars
80	0.45	40	0.19
90	0.45	46	0.19
100	0.38	34	0.13

Data on which Table 2 is based.

Labor cost: Millers, 40 cents per hr.; drier firemen, 35 cents per hr.; common labor, 35 cents.

Cost of drier fuel: 6 cents per net ton, based on 7 per cent. moisture. Coal at $5 per ton delivered.

Evaporation: 6 lb. per pound of coal burned or 26 lb. of coal per ton.

Repairs: 7 cents per net ton; this includes whole pulverizing plant, all machinery.

Power has been based on 12.7 per ton pulverized, and a consumption of 17 h.p.-hr. per ton pulverized at 1 cent per k.w.-hr. or about $54 per h.p.

Cost of pulverizing will naturally vary according to local conditions.

successfully to various kinds of heating furnaces, including forging, continuous-heating, busheling, puddling and open-hearth furnaces. Pulverized coal is being used on continuous-heating furnaces with very gratifying results. It is also being used as a fuel for soaking pits and promises to be used more extensively on this type of heating furnace in the future.

One of the first applications of pulverized coal to the various types of metallurgical furnaces was made by the American Iron & Steel Manufacturing Co., now the Bethlehem Steel Co., Lebanon, Pa., at whose plant this form of fuel was successfully applied to heating, busheling and puddling furnaces, this being practically the first attempt to apply it to the iron and steel industry. Taking into consideration the knowledge obtained from the experience at the above-mentioned plant, and also that obtained from other installations, it has been found that furnaces can be successfully operated by various methods of applying this fuel. Each type of metallurgical furnace presents different requirements as to the kind of burners to be used. Probably the greatest recent development in its use has been as a fuel for open-hearth furnaces and boilers.

Boilers

Many engineers who attempted to burn coal in pulverized form obtained unsatisfactory results, and concluded it was "impossible." In many of the earlier trials to burn pulverized coal under boilers the usual method was to install coal-feeding devices of some kind in the furnace as it stood, with the result that the fire bricks melted down and the tubes were plastered with unconsumed carbon, ashes and soot. So destructive were the results that we can hardly blame those making the tests from arriving at the conclusion they did. How close some were to success was not fully realized. Conditions were not ripe. To-day, results are being obtained that are of sufficient importance to warrant careful investigation and consideration.

For the proper combustion of coal under boilers, there are five main points which must be given serious consideration, otherwise the burning of this fuel will not be a success. These five points are:

a Coal fineness
b Size of combustion chamber
c Necessary air opening
d Proper damper regulation
e Clean tubes

Coal fineness. The pulverized coal should run about 96 per cent. through the 100-mesh screen and about 85 per cent. through the 200-mesh screen. If it runs below 80 per cent. through the 200-mesh screen, we notice particles of carbon flying through the air inside of the combustion chamber, and these particles are not completely burned when the gases reach the tubes, and will then deposit themselves on the tubes. Also, these heavy particles in the pulverized-coal mixture will sometimes settle on the bottom of the combustion chamber and will soon build up in the shape of stalactites. This accumulation will continue to build until the bottom of the combustion chamber continues to be raised, until it comes in contact with the flame. These built-up particles will then fuse into a solid mass, which, in a very short time, will cause a shut down of the boiler to dig this fused mass out. It is, therefore, necessary, for the successful burning of this pulverized fuel under boilers, to have this coal as finely pulverized as possible.

Size of Combustion Chamber. Before installing, or considering the use of pulverized coal under boilers, we must first make a study of our boiler-house installation and know at exactly what rating we wish to operate these boilers, considering any peak load which may develop. We must then design our combustion chamber large enough to take care of the maximum loads which will be developed from our boilers at any time. After this maximum rating has been determined, we then figure our combustion chamber of a cubical capacity equivalent to approximately 50 cu. ft. per lb. of coal burned per min., or approximately 2½ cu. ft. per h.p. developed by boiler. If we decide to run this boiler at 150 per cent. of this rating and design our combustion chamber accordingly, the efficiency will not be decreased perceptibly if the boiler is run under this 150 per cent. rating, but if we develop over a 150 per cent. of the rating, we run into serious difficulties. We have to admit more coal and air to the boiler to develop the greater rating, consequently we need more combustion space, but not having this combustion space, the flames impinge on the brick work and cut it away very rapidly. Also, combustion is not complete at the time the gases strike the bottom row of tubes and consequently the gases will pass up the stack unburned. Efficiency is then decreased. If the gases are not completely burned by the time they reach the first row of tubes, they will not burn later on in the boiler. The size of the combustion chamber should also be so designed that the velocity of the gases should not pass through this combustion chamber at a speed of more than 6 ft. per sec. The mixture of air and coal entering the combustion chamber, as stated above, should be at as low a pressure as is possible to bring this mixture in in suspension; or, in other words, breathe it in.

TABLE 3. COSTS OF PULVERIZING COAL PER NET TON AT THE ATLANTIC STEEL COMPANY.

	Cost per ton.
Daily Output 80 Tons per Day.	
Labor	$0.22
Repairs	0.19
Power	0.134
Drier coal	0.0218
Total Cost	$0.5658
Daily Output 90 Tons per Day.	
Labor	$0.195
Repairs	0.19
Power	0.134
Drier coal	0.0218
Total Cost	$0.5408
Daily Output 100 Tons per Day.	
Labor	$0.176
Repairs	0.19
Power	0.134
Drier coal	0.0218
Total Cost	$0.5218

Total coal pulverized Jan. and Feb., 1919 ..... 5275 tons

Power: 17.9 k.w-hr. per ton pulv. at ¾ cent ..... $0.134 per ton

Labor: 1 man 16 hr. at $0.40 ..... $ 6.40
2 men 16 hr. at $0.35 ..... 11.20

Daily cost $17.60

(= $0.22 for 80 tons output, $0.195 for 90 tons, $0.176 por 100 tons.)

Drier coal: Cost of drier fuel 2.8 cents per ton, based on 2.62 per cent. moisture. Coal at $5 per ton, 6 lb. evaporated per lb. of coal burned or 8.7 lb. per ton of coal pulv.

Repairs: Total repairs for Jan. and Feb... $1412.16
Credit 409.69

Charged $1002.47
(= $0.19 per ton pulv.)

Proper Air Openings. The pressure at which the pulverized coal is admitted to the furnace is as low a pressure as can be used to carry this fine coal in suspension, and is, I should say, about half an ounce pressure at the nozzle. In some installations the coal falls by gravity from the variable-speed screw conveyor, located on the bottom of the pulverized coal bin, into a fan air line which carries it into the furnace and also supplies the necessary air for combustion. Some few openings are placed in the front wall of the boiler to give any additional air which may be needed, and a few may also be placed on the side walls of the boiler to protect the brickwork at times.

In other installations the amount of air necessary to convey the coal into the furnace varies, acording to the rate at which the boiler is being operated. The balance of the air to burn the coal properly is admitted through adjustable air openings in the front, sides and bottom of the combustion chamber. These openings are made adjustable and are placed on all sides of the combustion chamber to take care of the various grades of coal which may be used in the boiler plant. By properly observing the combustion in this chamber, by a little experience the fireman knows at exactly what points to give more, or less air needed for combustion.

Damper Regulation. In order to give the proper velocities of gases passing through the combustion chamber, it is necessary that we have very accurate damper regulation to take care of the various load conditions which the boiler is to supply. The damper should be so regulated that we should practically have a balanced draft inside of the combustion chamber and only a slight vacuum in the first pass, while at the damper itself we do not want more than 0.10 to 0.15 in. If we have more vacuum than this, it pulls our gases through the combustion chamber too fast, causing them to be unburned before reaching the first row of tubes and will then build up very fast on the outside of these tubes. This very small draft needed at the base of the stack will allow us to operate boilers using pulverized coal with stacks of about 30 to 35 ft. in height.

Clean Tubes. In order to get the

maximum evaporation from any boiler it is necessary that the tubes be kept clean, both inside and outside. The keeping of the tubes clean inside is a question of the proper quality of water and has nothing to do with pulverized coal. The keeping clean of the outside of the tubes is very necesary with the use of pulverized coal as a fuel, and they should be blown by means of mechanical soot blowers at least every six hours, and oftener if it is necessary. Also, once every 24 hours by means of a hand-lance steam jet we should blow the bottom of the first row of tubes. These are the tubes in which the gases come into contact first after leaving the combustion chamber has been properly constructed and if they are blown regularly as needed. But if they are not blown regularly this material builds up and accumulates very fast and in time will become fused and cannot be blown off.

Another item which might have been included in the five main points above, and might have been called the sixth point, is the removal of ash which deposits at the bottom of the combustion chamber. As spoken of above, this ash should be removed at regular intervals, which intervals will be determined by the amount of ash in the original coal. If we do not remove this ash regularly, it will build up until it comes in contact with the flame, when it becomes fused and has to be dug out. But if removed at regular intervals, it can be easily raked out with ordinary boiler-room ash rake and will not consume more than half an hour per 24 hours, and will not interfere with the operation of the boiler while this is being done.

The following are some advantages of pulverized coal as a fuel for boilers over stokers:

(a) Muhc wider variation in the quantity of the coal usable is obtained when burning coal in pulverized form. Practically any and all grades of coal can be burned in this form with economy. No stoker will satisfactorily handle all grades of coal. Therefore the use of pulverized coal will largely overcome most troubles due to poor coal, and it is particularly desirable for this reason alone.

(b) The ability to take care of peak loads almost instantaneously. In other words, a pulverized-coal burning system is much more flexible than a stoker in stallation. Its flexibility approaches that of oil or natural gas.

(c) The amount of coal that can be burned per sq. ft. of grate surface on stokers is limited so that for increased capacity the boiler setting must be spread out to cover more area. When using pulverized coal, this condition does not exist, for proper furnace conditions can be obtained by increasing the height of the boiler setting or the depth of the combustion chamber.

(d) By throwing a switch the entire firing operation ceases; an advantage in case of accident or emergency.

(e) Ash is in much better condition to handle. The ash is in the form of a dust or slag depending upon its melting point. This helps to maintain constant furnace temperature as there are no interruptions to firing conditions on account of cleaning fires.

(f) Since there are no grates used when the fuel is burned in pulverized form, we experience no clinkering of grates, as in the case of stokers, particularly after operating at maximum rating.

(g) Pulverized coal is fired dry, containing less than 1 per cent. of free moisture, whereas coal burned on stokers may vary anywhere from 1 to 10 per cent., of free moisture as fired.

(h) Considerable less excess air is necessary for complete combustion. This item is of the utmost importance when making comparisons. Less excess air means less power for furnishing air supply particularly where forced draft is used. With less excess air the stack losses are less. Lower grades of coal fired on stokers require more excess air as it is quite difficult for the oxygen to get in close contact with combustible. An air supply sufficient to furnish all the air for combustion should be available, although at times only 50 per cent. of the air is necessary to be injected into the furnace with the coal, the balance being supplied by the induction action of the burner or drawn in by the stack draft through the various adjustable openings in front and sides of combustion chamber. The air going into the furnace should be under control to permit close regulation under all conditions of firing. Less draft is required for pulverized-coal-fired furnaces.

(i) All the combustible in the coal is consumed when it is burned in pulverized form, providing the furnace capacity is not exceeded. None of the combustible goes out into the ash pile and therefore fires are eliminated in the ash pile.

(j) There is less erosion from sulphur on the boilers due to less moisture in the coal as fired, therefore high-sulphur coals can be burned more readily and without serious results.

(k) With furnace properly proportioned and with properly designed burning equipment smokeless operation may be maintained indefinitely. This is due to

PULVERIZED COAL AS A FUEL

TABLE 4. LOG OF TEST OF A PULVERIZED-FUEL-BURNING STATIONARY BOILER. DATE AUGUST 12-13, 1918.

Make of boiler			Edge Moor
Rated h.p.			468

Resulting net efficiency, per cent			81.1

*No deduction made for stand-by losses in drier.

complete combustion of all the particles of coal before coming in contact with the cold surface of the tubes of the boiler.

The following few points must be kept in mind for the successful burning of pulverized coal under boilers:

(a) A boiler furnace using pulverized coal should have as few burners as is possible consistent with good regulation. The burners must be proportioned for the maximum rating of the boilers, and they must be adjustable. Simplicity of design is desirable. It has been found much more desirable to introduce coal into the furnace as far away from the side walls as possible so that the rapid continuous expansion of the gases will not develop high velocities in close contact with the furnace refractories. Furnaces under boilers should be proportioned so that the velocity of the gases should not be excessive, particularly at the smallest cross-sectional area of the furnace. Vertical baffles should replace all horizontal baffles.

(b) A boiler of any size can be fired successfully with pulverized coal. Various designs and makes of boilers can be readily arranged for pulverized-coal firing, but those containing the smaller percentage of space for the lodgment of ash are preferable.

(c) Feeders for regulating the flow of pulverized coal to the furnace must be designed so that at all times the variation in quantity will be directly proportional to the speed of the screw and no flooding allowed. The speed of the feeder should be so regulated that operating at its maximum r.p.m. the supply of pulverized coal to the furnace will not exceed the capacity of the furnace. Soot blowers should be installed in settings where pulverized coal is used.

(d) The equipment for using pulverized coal is standard for any grade of coal so far as handling, preparing and delivering to the furnace is concerned. Only a slight change is necessary in the furnace to take care of coals of very low volatile content, such as anthracite, culm and coke breeze, and increased drying capacity is desirable when lignite coal is used. With stokers this is not the case as the varying quality of coals require different type stokers to obtain highest efficiency.

(e) The labor required to operate a pulverized-coal installation may be of higher class, but the number of men required will be less in the larger installations than that required for a stoker installation, thereby effecting a saving in the labor charge in favor of pulverized coal.

The following is a report of a test on a 468-h.p. boiler using pulverized coal as fuel. This installation is noteworthy not only by reason of the high efficiency obtained, but also because of the fact that it has made clear some of the conditions necessary for the successful operation of boilers utilizing powdered fuel.

When the boiler was first put into operation, a number of undesirable conditions resulted. An insufficient air supply caused high-furnace temperatures resulting in fusion of the ash particles and a consequent accumulation of slag between the tubes, on the furnace walls and in the ashpit. The removal of the molten slag presented considerable difficulty. It was also found that the combustion chamber was of insufficient size. High gas velocities resulting from insufficient air in the chamber tended toward destruction of the refractory surfaces of the furnace.

A new furnace was therefore designed. The combustion chamber was enlarged and a regulated air supply was provided for by means of a number of auxiliary air openings equipped with dampers. The accumulation of slag in the pit was prevented by raising the point of admission of the fuel into the furnace. As a result the flame path has been raised above the base of the pit, hence particles of ash dropping from the flame are not fused. The ash, therefore, can be drawn from the pit in the form of a powder and small slugs of slag. Analysis has shown that the ash contains practically no carbon.

Having established satisfactory furnace-operating conditions, a series of efficiency and capacity tests were conducted preliminary to proving the contact guarantees. The brickwork was then given a thorough trial by carrying the boiler at a continuous rating of 180 per cent. over a period of several days. On August 12 and 13 a final efficiency test, the results of which are given below, was run. The boiler is a three-pass water-tube boiler, equipped with a superheater.

At this same plant are other boilers fired by one of the most efficient types of underfeed stokers. A comparison is made between results of above test and tests made on the stoker-fired boilers.

Pulverized Coal vs. Mechanical Stokers

Under this heading fuel-preparation costs will first be considered. In the case of powdered coal this can be classed under three general divisions:

(a) The cost of crushing the coal. This expense is the same for pulverized-coal equipment as for stokers.

(b) The cost of drying and pulverizing the coal. Although no cost records are available at present, it is estimated that 32 cents per ton will cover this preparation cost on a 200-ton-per-24-hr. plant using bituminous coal containing about 12 per cent. moisture.

(c) The maintenance costs of the drying and pulverizing plant. This unit has not been determined from actual experience; however, it is estimated that 3 cents per ton will cover the maintenance. In stoker practice the maintenance cost per ton of fuel fired is close to 5 cents per ton.

Summarizing the above facts it is evident that, with fuel at $5 per ton, the gross efficiency shown by the pulverized-fuel boilers will have to exceed that shown by the mechanical-stoker-fired boilers by 6 per cent. in order to offset coal-preparation costs. A 6 per cent. deduction from a gross efficiency of 85 22 per cent. results in a net efficiency of 79.22 per cent. for the powdered-coal burner. In stoker practice the maximum attainable gross efficiency at any of our plants has been 80.54 per cent. Deducting the 2.5 per cent. for auxiliary uses, the resulting net efficiency is 78.04 per cent., which is lower by 1.18 per cent. than the figure obtained in pulverized-fuel practice.

Other advantages resulting from the use of pulverized fuel are summarized herewith:

(a) Continuous boiler operation at a uniform rating as well as a constant efficiency is made possible. At no time is there a loss in capacity due to the clinkering of coal on the grates or the cleaning of fires, as is the case in stoker practice.

(b) Heavy overloads can be taken on or dropped off in a very brief time through adjustment of the coal feeders and the furnace drafts.

(c) From 97 to 98 per cent. of the combustible in the coal is utilized, regardless of the quality of the fuel.

(d) The ash-handling costs are reduced to a minimum due to the reduced volume.

(e) The banking conditions when operating with pulverized coal are somewhat different from those obtained in stoker practice. By stopping the fuel supply and closing up all dampers and auxiliary air inlets a boiler can be held up to pressure for about 10 hours. The furnace brick work having been treated to incandescence during operation gives off a radiant heat which is absorbed by the boiler rather than being sent out through the stack. The ease of controlling the fuel, feed and drafts, the ability to take on heavy overloads in a brief time, the thorough combustion of the coal and the uniform high efficiency obtainable under normal operating make pulverized coal a most satisfactory form of fuel for central station uses.

The full story of maintenance expense is only partly known as yet, however. Indications are that no unusual difficulties will be met. The cost of fuel preparation and labor for operating a boiler room fully equipped with pulverized-coal-burning boilers will be a question for the engineer to decide for himself according to his particular conditions. If properly installed with respect to capacity of storage, size of drier and pulverizers, and on a sufficient number of boilers to properly and fully employ the minimum number of men, the pulverized-fuel installation will undoubtedly be more advantageous. The main item that must be borne in mind by engineers is that the ease with which a high efficiency is obtained and the constant nature of that efficiency, as compared to the lack of constancy of efficiency in a stoker-fired boiler, unless very closely supervised, is the one factor about the burning of pulverized fuel which justifies its use. There is no doubt that with a well-equipped plant burning pulverized fuel, having all the necessary recording and indicating instruments to guide the operators in maintaining the proper conditions, a lower cost of generating steam will be possible than has heretofore been the case in any type of equipment.

The Cross Drum Type Heine Water Tube Boiler

Description of the Boiler as Fitted in the Ships of the United States Emergency Fleet and Other Vessels—The Cross Drum Type Has Proved Very Satisfactory in Service

MARINE boilers of two types ave been built by the Heine Safety Boiler Company in their plants at St. Louis, Mo., and Phoenixville, Pa. —the "longitudinal drum" type and the "cross drum" type.

The former is built on the lines of their well-known Heine water tube boiler and the earlier ships were fitted with these, but the later and by far the greater number of ships have received boilers of the "cross drum" type, which has shown itself so superior for the peculiar and exacting marine service that it is now the Standard Heine Marine Water Tube Boiler.

The boiler proper consists essentially of three pressure elements joined together by a multiplicity of tubes. These elements are two flat rectangular box headers and a cylindrical steam drum, as shown in Fig. 1.

The main bank of tubes extends between and connects the two box headers, which are set with the flat surfaces a certain distance apart. The connecting tubes are all of the same length, straight and parallel with each other, and when this part of the boiler is set in operating position, are inclined at an angle of sixteen degrees to the horizontal.

Above the front box header and slightly to the rear of it is placed the steam drum, which is connected to the front header by a row of nearly vertical short tubes or nipples and to the rear header by a row of longer tubes, which are horizontal when the boiler is set.

The boiler proper, made of drum, box headers and tubes, is supported by a strong, rigid, steel structure resting on and secured to proper foundations in the vessel—partly shown in Fig. 3.

The steam drum is cylindrical and varies in the several sizes of boilers from 36 in. to 48 in. in diameter. It consists of a single plate steel shell of a thickness corresponding to the pressure requirements, rolled to a true circle, fitted with a double-riveted, double butt-strapped longitudinal riveted seam and at the ends with flanged and dished steel heads which require no braces. In one of these heads is arranged a flanged-in manhole for access to the interior of the steam drum.

Where the tubes enter and are secured to the shell of the drum, reinforcing plates are fitted. On top of the drum are fitted heavy pressed steel saddles for attaching the main stop valve, auxiliary stop valve and safety valve.

To the front side of the drum shell are riveted pressed steel flanges for attaching main and auxiliary feed check valves, surface blow valve, two water gauge glasses and three test cocks.

Inside the drum, properly secured to shell and firmly braced in position, is fitted a steel deflection plate. This plate is of sufficient length to cover the ends of the horizontal tubes and extends below the water level, its purpose being to act as a separator for the mixture of steam and water entering the drum through the horizontal tubes. The water thrown violently against this plate runs downward into the body of water below and the steam passes along and around the ends of the plate and to the dry pipe above.

An internal feed pipe is fitted between the feed check valves. This is perforated in order to distribute the entering feed water uniformly through the water already in drum to avoid producing undue strains. The same pipe is connected in both checks.

A scum pan of the usual "dish" type with its cover plate slightly raised to produce an efficient "skimmer" effect, is located at the centre of the drum, exactly on the water line, and piped to the surface blow outlet on the front of the drum shell.

Surge plates are fitted to check the rush of water along the drum as the vessel rolls in a seaway. These plates, together with the deflection plate, make a substantial structure for supporting and securing the various fittings within the drum.

The main steam outlet is provided with a dry pipe of ample area. This pipe is fitted as near the top of the drum as practicable and has slots cut through its upper side, the area through these slots exceeding the area through the outlet opening. Calorimeter tests show that the Heine marine boiler thus fitted delivers steam containing less than three-quarters of one per cent. of moisture.

Zinc slabs are also fitted in the drum of the Heine marine boiler. The Navy standard of three-quarters of a square foot of exposed zinc plate is provided for each one hundred square feet of heating surface of the boiler. These zinc plates are secured so as to give close metallic connection with the metal of the boiler and yet allow easy renewal. A pressed steel "basket" is also fitted to catch the disintegrated zinc.

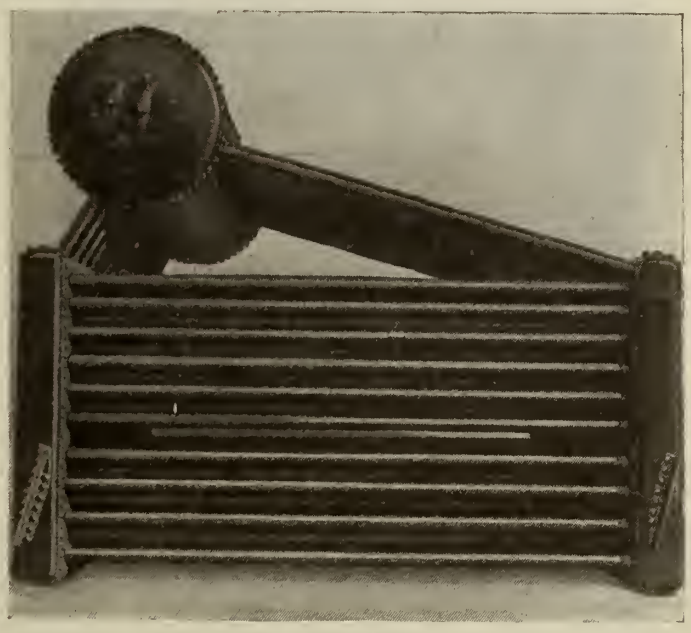

FIGURE 1

Zinc plates are fitted to a marine boiler to act as a negative element of an electric couple which is formed when it and iron or steel are placed in a saline liquid. It is impossible to keep boiler water in the ocean service absolutely fresh, and if correctly fitted, zinc thus avoid pitting and deterioration of boiler plates from electrolytic action.

The box headers are constructed entirely of steel plate. Each consists of two flanged rectangular heads or end plates to which are riveted a wrapper plate in two pieces. These headers are so designed that all seams are readily accessible for inspection and recaulking without tearing away the boiler casing.

The end plates are flanged by hydraulic pressure at a single heat and are of the exact shape desired. The two wrapper plates, known as the tube sheet and the handhole sheet, have their edges turned over at the top and bottom

of the headers, lapped and riveted together with a single row of rivets; with caulking edges facing outward.

The flat surfaces of the tube and handhole sheets are truly parallel with a hand hole exactly opposite each tube hole, thus permitting access to the tube for cleaning and withdrawal of tube through the handhole when necessary.

The two flat surfaces of the box headers are stayed to resist internal pressure with large hollow steel stay bolts

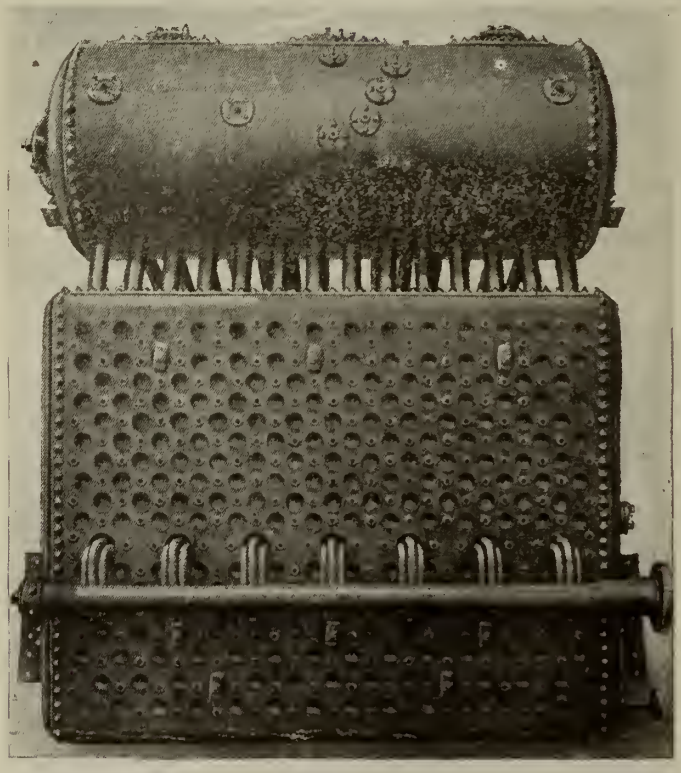

FIGURE 2

screwed through tapped holes in the plates, and with the projecting ends of stay bolts riveted over on the outside.

The stay bolts are threaded only at the ends, leaving a smooth cylindrical shank within the water space, thus offering no sharp edges or grooves to the corrosive effect of rust. Each stay bolt has a hole throughout its entire length of ample size to pass freely a ⅜ in. pipe lance for soot blowing.

Forged steel tee bar lugs (see Fig. 1), of heavy section. about 24 in. in length, are riveted to the outside of each flanged end plate of the headers for attachment to the supporting columns of the casing structure.

The flat bases of these tee bar lugs are caulked all around and the edges are ever accessible for inspection or recaulking without tearing out any part of the boiler support or setting.

Near the bottom of the front (lower) box header and on one side only (except in extremely wide boilers) is riveted a forged steel flange to which is bolted, with copper gasket in male and female joint, a heavily ribbed and flanged composition blow nozzle or extension pipe to the outer end of which is attached the bottom blow valve. An internal pipe leads to the extreme bottom of the box header and insures removal of sediment deposited therein.

The standard design of Heine marine water tube boiler has 3½ diameter tubes throughout.

For oil fuel only, they recommend the use of 2 in. tubes instead of 3½ in. tubes in the inclined bank between the headers, and build a special oil burning marine boiler so fitted.

They do not recommend the use of 2 in. tubes for coal fuel because of the great tendency of boilers fitted with small tubes, closely pitched, to "soot up," or become choked. Its superior steaming qualities are recognized. However, it is a fact that by the use of 2 in. tubes equal heating surface can be obtained in a boiler of much less height than is possible when larger tubes are employed.

They fit the Heine marine boiler with standard lap welded steel, charcoal iron, or seamless steel tubes, as the owner may prefer.

For low or medium superheat, Heine marine boilers are fitted with superheaters of the "waste heat" type placed in the base of the up-take, as near as possible to the exit of the gases from the boiler. For higher superheat the elements must be placed where they will be in contact with gases of higher temperature and are often fitted just below the middle baffle, the superheater elements passing through the 5 in. stay tubes between headers located outside the boiler (see Fig. 2). The right angle bend of the superheater tubes entering the top of the front pipe header is arranged at one end of the boiler only and permits of the tubes being more easily removed and replaced than if they were straight throughout.

Heine marine water tube boilers are built in accordance with the rules and regulations of the United States Board of Supervising Inspectors and are approved by Lloyd's Register of Shipping and the American Bureau of Shipping. When desired by the purchaser, either insurance company or purchaser is permitted free access to their works and given every opportunity for inspection and approval of plans and material entering into the construction of boilers

The setting of the Heine marine boiler consists primarily of a framework of rolled steel shapes so constructed that the four main columns, one each side of each box header, are tied together and braced, and thus secured rigidly against relative motion of any sort. These columns are secured at their bases to seatings prepared by the shipbuilder, the structure described forming a cradle within which, secured by the four tee bar lugs, the boiler proper is supported.

A steel plate casing is built upon this framework, entirely surrounding and covering the boiler and furnace with the exception of the drum. That portion beside the bank of inclined tubes is fitted in panels that may be readily removed for access to the brick lining, and a sectional bottom plate, that may be easily renewed, is fitted below.

The interior of the whole is lined with fire brick, non-conducting material or a combination of these. All parts are carefully fitted to prevent the ingress of undesirable air.

Where grates are furnished for coal fuel, a watertight pan is also fitted in the ashpit, but for oil burning installations the furnace space is made as large as possible. The casing about the furnace proper is lined with refractory walls 12 inches thick and above the lower baffle the lining is 7½ inches thick.

The furnace fronts for coal burning are fitted with balanced in-swinging doors above and below the grade. For oil burning the front is usually a steel plate with openings of suitable size cut to take burner castings.

When installed and ready for operation the Heine marine boiler is filled to the middle of the steam drum with water. The circulation is downward in the front box header and upward in the rear box header, upward and back in the lower majority of the bank of inclined tubes and downward and to the front in a few upper rows of inclined tubes; the steam parting from the water in the upper portion of the rear header and passing into the steam drum through the horizontal tubes as before described.

With this steam there is some quantity of free water which is separated and thrown down in the drum, the steam passing about the ends of the deflection plate to the dry pipe, the water passing down through the short tubes circulating water, it again passes through the lower inclined tubes.

Feed water entering the boiler issues

FIGURE 3

from the perforations in the internal feed pipe in jets, and is thus thoroughly mixed with the water in the drum before passing downward.

Should oil or impurities enter with the feed the scum formed may be removed by operating the surface blow with water level at middle of the glass. Sediment will be thrown down in front header, where the bottom blow is arranged to remove it.

Scale is removed from the tubes by using a hydraulic turbine cleaner, which, together with the necessary hoses, is provided with every boiler.

All boilers that are not too large are assembled complete at the manufacturer's shops before shipment. Usually, however, the clearance limitations of the railroads do not permit of complete assemblage and the drum and its connecting tubes must be fitted in place at the point of installation.

All parts are subjected to a hydraulic test of twice the safe working pressure before shipment. The work of fitting the drum at the ship's side or on board consists merely of inserting and expanding a few tubes.

The casings are assembled complete before shipment and knocked down after match-marking the various pieces so one cannot go wrong in re-erecting them at the shipyard.

When provisions at shipyard for handling the heavier pieces are inadequate and customer desires, the boilers will be shipped entirely knocked down. To assemble them aboard the ship will then be merely a job of rolling all tube ends, as the headers and drum will be complete in all respects.

ARMATURE CHOCKS

Several years ago at a power station a 600-kw. spare armature was laid in specially built wood chocks. These chocks were made of oak for strength. After the armature was laid in, the shafts were smeared in vaseline. Quite recently, when the armature was lifted out, the shafts were found to be seriously pitted (about one sixty-fourth in. deep) all along the shafts where they had touched the chocks.

This was caused by the acid action of the oak.

REMINDERS WHEN MAKING CONCRETE FOUNDATIONS

The following hints will prove useful to readers who may have to lay down concrete foundations for machinery or plant:

Get well down to firm soil before starting a concrete foundation, and do not stint it either in length or width. A one-piece foundation, though it might cost extra to make, invariably gives more satisfaction than a disjointed or sectionalized one. Two or more beds not fully integral can be stiffened and more firmly braced by building in short lenghts of old rails, tee, angle, or channel bars as reinforcement. Leave plenty of clearance in bolt holes. Use square-necked bolts and washer plates of ample area. The form boards for moulding above ground parts of a foundation must be sufficiently thick and well braced to prevent bulging and warping under the weight of concrete. The more irregular the faces of the excavation the better will be the grip of the bed. Well ram each "gauge" down with a bar of rammer, so as to force the material to the outside of the bed. Do not be afraid to have the concrete wet enough to run; a little excess water will not matter in the least. If possible, run the entire foundation without a break; but if this cannot be arranged well, wet the top of the old layer before starting with the new, and leave the face rough—the rougher the better. Do not remove the form boards under three to four days from the time of moulding; then wet the faces of the concrete every day for a week in order to prevent premature surface hardening and cracking.

For rough work, slow moving machinery, and where chances of vibration are not likely to occur—a mixture of one part cement, 3 parts sand and 6 parts broken down, or coarse gravel, makes a good concrete. For higher class work—high speed machinery, engines, generators, turbines, motors, etc., a better mixture would be 1, 1½, 3, respectively. One still better is 1, 2, 4. See that the cement is fresh and has not been exposed to the air. If any doubt of it exists, test a little for hardening time. Use well-washed, hard, sharp sand, and clean good stone with no dirt intermixed. Remove all loose, soft, rubble or old mortar. A good plan before preparing the concrete is to wash all gravel and stone with a hose. Do not hurry the setting of a foundation by employing artificial heat, or it may crack. Protect a newly-made bed from frost by covering it with dry sacks. The quantity of material required for a foundation of a given cubic content is generally reckoned as the approximate quantity of stone, since the sand and cement adds little to the bulk, but is taken up in the many interstices formed by the stones. In mixing each "gauge," adhere closely to the determined proportion. Use a square frame, having a known cubical content for measuring the material before mixing.

Face all above-ground parts of the bed when dry with a "wash" of 1 part cement to 2 parts fine sifted sand, and apply with a brush. If a machine requires to be grouted in subsequent to being set in position on the foundation, the top surface of the latter is best left quite rough, in order that the grouting material shall firmly adhere. Roughening or grooving the face of the concrete with a pick or pointed hammer is an advantage. Rounded corners of a bed are preferable to square, both for the sake of appearance and as a protection against wear and chipping.

PREVENTING THE GROWTH OF CAST IRON

Amongst the fascinating problems which make engineering science at once a most exacting and a most fruitful study, the characteristic behaviour of metals under varying conditions provides many curious cases. For example, grey cast iron grows appreciably in volume when exposed to high temperature. This characteristic, which causes much trouble in cast dies, valve seatings and other parts, is believed to be due to internal oxidation caused by the penetration of hot gases into the metal. A remedy recently suggested in England is to eliminate free graphite from the surface of the metal, this being the cause of its prosperity. Successful results have been obtained by annealing the parts for several days in iron rust at a temperature of from 1,650 to 1,830 degrees Fahrenheit.

Oil to the Rescue

GREAT stress is being laid these days on the possibilities of oil as fuel to replace coal. The coal situation is becoming acute in every country in the world, and in Great Britain, where coal has for so long been king, it is felt more than in most places. The recent disastrous strikes, coupled with the constant fall of production due to shorter working hours, has caused widespread alarm among all sections of the population, except perhaps among the striking miners. These are evidently of the same frame of mind as the Irishman who, when being lowered down a well, demanded to be pulled up. He backed up his demand with the statement that if it was not complied with he would cut the rope.

The value of oil has been appreciated for a long time now, but one of the reasons it has not been used more generally for fuel aboard ship has been the lack of suitable fuel oil stations in different parts of the world. This is being rapidly overcome, and if the present boring operations in Great Britain result in the discovery of an adequate supply, the situation will be materially relieved. Oil, whether used as fuel for a steam boiler, or directly in the cylinders of an internal combustion engine, is a much more satisfactory fuel than coal. It is more easily and quickly handled than coal, and its heat value is about one-third greater. Combustion is carried out more efficiently than with coal, and there is an entire absence of smoke. The cruising radius of a steamer fitted with oil burners is considerably more than when coal burning, the crew required is less, and the oil can be carried in ballast tanks instead of occupying space that could otherwise be devoted to profitable cargo.

On shore there are a great number of uses for it. Besides being available for steam-raising purposes, it is the best and most economical medium for supplying heat to metal-working furnaces, for tempering, annealing, enamelling, etc. Mixed with the finer refuse of the coal pit, it makes a colloidal fuel of great value. We may look forward to the next few years for great developments in the use of this fuel, which provides a means of obtaining our power at a much higher rate of efficiency than we have been accustomed to getting with the use of coal. It should not be long before it can be applied safely and economically to the heating of houses, to the great relief of the average citizen of this country of long winters.

Boiler Corrosion

AS an instance of the obscure nature of boiler explosion the following instance may be cited. Corrosion commenced after a few months' operation in the drums of the water tube boilers of a 40,000 H.P. turbine installation in Germany. The make-up as well as the first charge of water was distilled and the water was, therefore, exceptionally pure. Corrosion was found to be particularly severe at the horizontal centre line of the drums. The tubes were ordinarily covered with rust, small pieces becoming detached by the use of wire brushes. The corrosive action was intensified when the turbines were worked intermittently with boiler pressure and vacuum maintained, the formation of blisters increasing and pitting becoming severe.

Another group of boilers fed with slightly oily water was found to be entirely free from corrosion, and the fact that boilers fed with condensate from reciprocating engines usually keep in good condition while the condensate from turbines sets up active corrosion, coupled with the action of the second group of boilers, led to the decision to produce a slight greasy deposit in the boilers by injecting oil through a sight feed arrangement. In addition all air was removed from the feed water. These precautions proved entirely satisfactory and corrosion ceased.

Is He Right?

By JAMES E. NOBLE

If you would a searching go to get an engineer,
There are some things to notice though seeming rather queer.
In going through the plant wherein there is a chap
Anxious for a change, to go another lap,
Have a look around the place, at him, too, have a look,
And notice if he dozes off in some sequestered nook.

And notice very carefully, this is the proper "cheese,"
If his pants have patches on the rear or patches on the knees.
Perhaps his clothes may look quite neat, the pressing neatly done;
His hands and face may be quite clean, he may be chewing gum,
But notice if the joints around the plant are good and tight;
And also notice if the charts and other things are right;
Note if the polished surfaces are shining bright and clear,
That everything looks spick and span with no dirt there or here.
The rear part of his trousers examine if you please,
And don't forget to note with care the trousers at the knees.

The man who stands upon his feet attending to his work,
Or wears his pants out at the knees is surely not a shirk;
But when the bearing surface of his breeches at the back
Begin to show a glassy shine around the baggy slack,
The time for careful thought has come, just give him the go-by;
Tell him the time has not arrived for him to change his sty;
Tell him that things are not just right, just tell him if you please,
His pants are too bright on the base and too rough upon the knees.

Meeting the Boss

(A Part of Reconstruction)

By C. H. STEPHEN

Did you ever try to approach the boss
In the way a real man should?
When you guess his gains, do you figure his loss?
As you might, if you only would?
Have you thought, as you envied him his "snap,"
Of the lots of hard spots in Dame Fortune's lap?

Can you always say at the end of the day,
You have taken a real man's stand,
And worked just as hard when the boss was away
As you do when he's close at hand?
Have you ever found, when you get in a pinch,
That being the boss ain't so much of a cinch?

Have you ever figured that most of the men
Who are now in authority
Need not look far back to the working day,
When they labored like you and me?
Have you ever thought that 'most every man's use
Can be based on the product that he can produce?

Have you ever found, when you carry a chip
On your shoulders the whole day long,
You tire much quicker with snarls on your lip
Than when your heart carries a song?
Have you yet discovered that friction of toil
Disappears when you use human kindness for oil?

Did you ever try to face squarely the fact,
With justice and truth in view,
That if you are square in thought, deed and act,
The world will be square with you?
Dame nature taught mankind, long years ago,
That the harvest increases the foul seed we sow.

Have you ever thought that most of the wrongs
That you to the boss ascribe
Would vanish if only your heart held more songs
And your mind fewer diatribes?
If you banish envy, and think what is good,
You can then meet the boss as a real man should.

—"Power Plant Engineering."

Speakin' of Profiteers

THE thing that's takin' lots of time and makin' lots of smoke, is the effort that's being made just now to corner certain folk who have been makin' dollars quick and grabbin' of the cash, while others strive to keep alive on sawdust, hay and hash.

They crooked a finger at some prune who ran a butcher shop; he had been gouging folks at home, he made them pay the shot.

He looked the judge right in the eye and waved his fist about, and opened up his sturdy jaw as though to hoot and shout. But then a tear stole to his eye, his voice was soft as lard, his heart was tender as a stew, his countenance not hard.

"Nay, nay," he said, "I am not he who profiteered, by heck, nor soaked the common horde for fair, nor camped upon their neck." Another tear chased down his face and crawled across his jaw, to think that folks suspected him of comin' 'gainst the law.

And then they brought a farmer, an honest son of toil, who gouged great holes into the folks, likewise into the soil. Oh, he had bought a joy cart new an' built a new bank barn, and likewise he had carved into the mortgage on his farm. But, bless my soul, he had not made no profits worth the name; his pickin's, so he said, were poor and most uncommon tame.

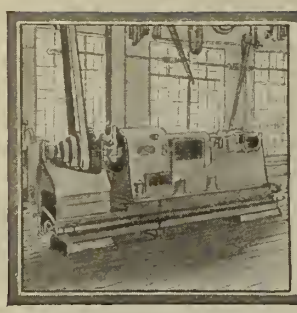
And so they had a whole procesh to try and find the chap who'd led the profiteerin' biz and staked it on the map. But, good land sakes, he was not there at mornin' nor at night, the chap who'd took the family purse and bled the hang thing white.

I long to see some hardy soul arise and make a bow, and in a voice that's noisy like, far more so than a cow—announce that he's a profiteer, a guzzler and a crab, who'd taken all the things in sight he had a chance to grab!

I would not hiss this chap, oh, no; nor would I heave a brick, nor take my heavy working shoe and aim at him a kick. Nor would I clamor for a chance to smite him on the jaw, nor ask that he be turned unto the 'steenth kind of law.

Far rather would I take my axe, my chisel and my hoe, and then unto some lofty place I'd grab my plans and go, and to this honest, kindly soul who owned up to the graft, I'd raise of granite and of gold a tall and glistening shaft. And on the thing I'd carve a verse, perhaps, in way uncouth, to tell the folks what's yet to come of him who spoke the truth.—ARK.

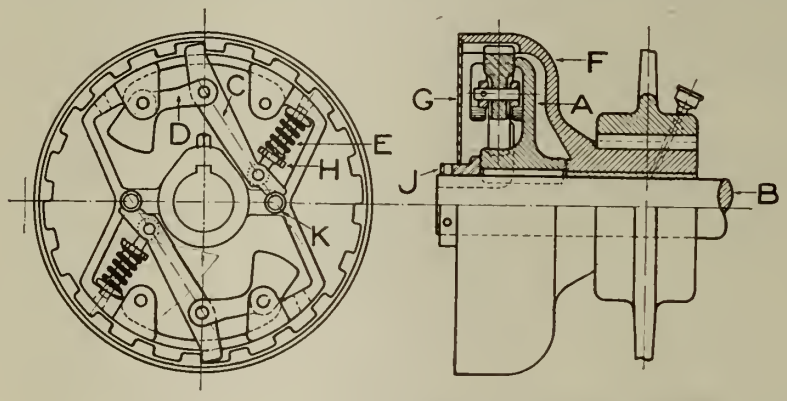
In dealing with the improvements which have been effected during the war in the construction of internal-combustion engines, Sir Dugald Clerk, in a paper before the North-east Coast Institution of Engineers and Shipbuilders, points out that towards the end of the war nearly 3,000 aircraft engines were produced in Great Britain per month, and in consequence, all internal-combustion engines were greatly improved in detail, so that the dry weight of these motors was reduced from about 4 lb. to 2 lb. per b.h.p. developed. Air-cooled engines became possible when mean effective pressures were employed equal to those of the best water-cooled engines. The h.p. value, that is the mean pressure equivalent of the brake horse-power developed in water-cooled engines, had risen to 125 per square inch of piston area by the middle of 1916, and the same h.p. value was obtained in air-cooled engines at the end of 1917. The struggle between the rotary and the six-cylinder radial engines was very keen, and recently it appeared probable that the latter would prove so advantageous in both military and mechanical properties as to displace all other types.



NEW POWER PLANT EQUIPMENT

MECHANICAL OVERLOAD RELEASE

The Link Belt Co., Chicago, Ill., have recently developed a safety device that will instantly disengage a drive if the load exceeds a certain pre-determined amount. This apparatus is better than a circuit-breaker, because it is placed



MECHANICAL OVERLOAD RELEASE.

closer to the work, and where it does let go there are no inertia forces from high-speed moving parts to cause damage. It is also better than a break pin device, because it is adjustable to the work and can be set and reset without spoiling the adjustment. Careless operators often use a big bolt to replace a broken break pin and thus destroy its usefulness.

The parts are symmetrical and will thus run in any direction.

In the illustration, spider A, keyed to shaft B, has triggers C pivotally mounted on links D, with the ends engaging inside notches in rim of drum F, and roller K in hub of spider A. Springs E, regulated to any desired pressure by adjusting nuts H, hold ends of triggers on rollers K under normal conditions, but when the drive is overstrained, the compression of the springs will permit the ends of triggers to drop into position shown in cut below, releasing connections with rim F, and allowing the machine to stop immediately.

To set release triggers in driving position again, collar J is provided, having fingers which engage pins in lower ends of triggers C. By turning this collar by means of a spanner wrench, the triggers will be moved to the original position and the outer ends will at the same time enter notches in drum F, thus renewing the transmission connection.

Cover G, fitting end of drum F, encloses and protects the entire mechanism. Hub of drum F may be extended to receive wheel or gear, and have a bushing for running loose on shaft; or may be keyed directly to a separate shaft, thus forming a coupling device, in which either element may be the driver, according to the circumstances.

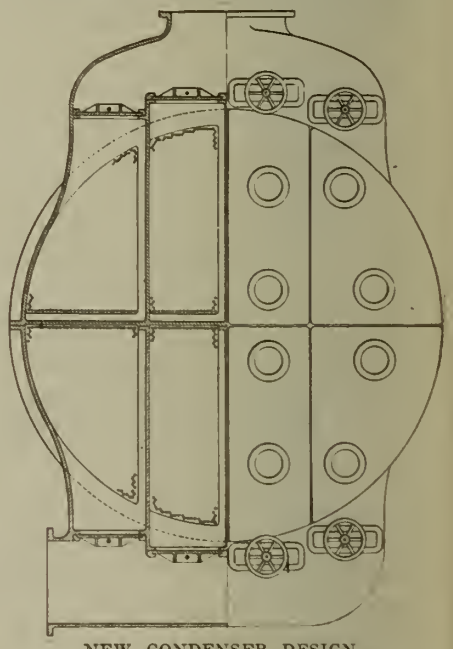
SOMETHING NEW AND GOOD IN CONDENSERS

A new and valuable development in steam surface condensers is announced by the Wheeler Condenser & Engrg. Co., Carteret, N.J. It is a patented "compartment condenser" that can be cleaned while in service without shutting down the turbine. Any tube or tubes may be temporarily plugged and other repairs made without taking the condenser out of service.

This is a timely development in view of the persistent claims made by well-known fuel authorities that the price of fuel is not likely to go down for some time, if at all. This condenser will enable the chief engineer to constantly maintain clean condensers, hence a constantly high vacuum. All engineers of experience know that in addition to increasing output a high vacuum means low fuel consumption and a considerable saving in money year in year out.

Also upon installation of this condenser there need be no interference with the operation of the turbine. At the present time, in many important power stations, even where water conditions are regarded as good, it is necessary to occasionally shut down the turbine for a period sufficiently long to give the condenser a thorough cleaning. In such cases, and in fact in all cases where continuous and highly efficient operation are desirable, this new type will fill a long-felt want.

To clean the average condenser is not a difficult task, but it is time-consuming, and for that reason the chief engineer is naturally tempted to put cleaning off until "to-morrow," or "next week," or "next month." During his wait for the opportune time the vacuum gradually drops, and with the drop coal wastage increases. Sometimes the loss of vacuum amounts to several inches of mercury.



NEW CONDENSER DESIGN

The illustration shows clearly how the compartments are arranged. The condenser shown is divided into four compartments, each compartment being equipped with a set of valves to control the circulating water. To clean the condenser while the turbine is delivering full power, the operator simply shuts off the water from one compartment, removes the cover, cleans the tubes, replaces the cover, turns on the water again, and then passes on to the next compartment, repeating the operation until the four compartments or the entire condenser is clean. Thus, while one compartment is being cleaned, the other compartments are in full operation, temporarily taking over the entire turbine load.

Peace-Time Exhibits in Machinery Hall C.N.E.

Manufacturers and Agents Have Representative Display of Power Plant and Industrial Equipment at Canadian National Exhibition

PEACE time activities are reflected in the various exhibits in Machinery Hall this year. The entire absence of shell machinery and munition-making apparatus is quite noticeable, albeit expected to those accustomed to the exhibits of former years. Space is again at a premium, and as usual comment unfavorable and forcible, is apparent at the inadequate provision made for the machinery industry. Much is in evidence of interest to the power plant operator, as the following partial list of exhibitors will show:

Exhibits

Geo. W. Cole, Ltd. are exhibiting the Cole steam trap in its various designs. Cross-section models of the working parts of these traps are shown, and a typical double trap boiler feeding installation, together with other features, render this exhibit interesting to the power plant engineer. Representative, Wm. H. Rose, Sam Craig and Geo. E. Cole.

The Dodge Co. are featuring steel pulleys, wood split pulleys, transmission chains, split clutches, hangers and bearings, conveyor material, gears, couplings, etc. Representatives, W. Burrows, S. M. Bowen, J. R. Gray.

Jones and Moore have a representative display of their various motors and generators and of the American shoe machine for which they are the agents. This firm handles a large stock of Century motors for all conditions of service.

The Canadian Ice Machine Co. have an excellent exhibit of refrigerating supplies and materials; fittings, ammonia, calcium, chloride, and other supplies being featured. This firm are the manufacturers of the York refrigerating systems and compressors, installations being made from ¼ ton up in the direct expansion, absorption or CO_2 systems, the latter being popular and of considerable adaptability for hospital and marine work.

The Cling Surface Co. are exhibiting for the eleventh consecutive year. The preservation and waterproofing of belts and the lowering of the friction load consequent upon the permissible slackness of the belts are shown to advantage by means of a one h.p. motor driving a three-plunger oil pump through a number of belts treated with cling-surface. Representative, G. W. Faatz.

The Chapman Double Ball Bearing Co. have, as usual, a most attractive exhibit of the various lines manufactured by them in the centre row at Machinery Hall.

In addition to the ball-bearing shaft hangers used in the line shafting, the exhibit includes bearings for all sizes of shafting up to six inches; also annular and thrust bearings for machinery, automobiles and trucks. Representative, Mr. Hocken.

D. K. McLaren Ltd., represented by Mr. W. S. Hamilton, sales manager, are exhibiting their line of single and double leather beltings, together with their waterproof varieties. In connection with these latter an interesting demonstration is given. Two belts are arranged to pass through pans of water while turning over pulleys. Other lines shown are the D. K. wood split pulleys, the Philips pressed steel split pulley and mill supplies for the carding, weaving and spinning trades.

The Goodyear Tire and Rubber Co. are showing a complete line of mechanical rubber goods such as their fire hose, extra service pneumatic hose, and Goodyear cord hose, extra power belting, packings, perforated mats, etc. Representatives, W. H. O. Crosby, F. Woods, F. Fox, and E. Dodge.

The Dominion Belting Co., Ltd., are exhibiting Maple Leaf brand stitched cotton duck waterproof belting for transmission of power and conveying. This is shown in various sizes, and excellent literature is distributed, showing its capabilities and endurance. Maple Leaf belt dressing is also on exhibit. Representative, John Scott.

The Hoyt Metal Co. are featuring their lead-lined and resisting products such as valves, centrifugal pumps. Together with this line they are displaying their various other lines of metal goods such as solder, babbitt type metal, etc. Representatives, G. F. Allen, manager; S. Wheatley and W. G. Downes.

The Lyman Tube and Supply Co. are featuring Shelby seamless steel tubing, together with the Chisholm and Moor anti-friction hoists. These latter are capable of 80 per cent. efficiency and are made in sizes up to 40 tons. Hyatt, Timkin and New Departure ball bearings are shown, together with electric railway supplies, made by the Electric Service Supplies Co. Chain belt and Rex products are also shown. Representatives, H. A. Jones, J. E. Openshaw, R. B. Bennett and Wm. Gardiner.

The John Hall & Sons, Ltd., Brantford, represented by Mr. Thompson, are showing several examples of their pipe threading machines. The large machine which can handle pipe from 2½ inches to 8 inches diameter is a fine looking piece of work, while the smaller sizes are also worthy of examination.

The Boiler Repair and Grate Bar Co., of Detroit and Toronto, have an exhibit of their shaking and dumping grate bars. These bars have been fitted in several local schools and public buildings. Mr. A. H. Hett and Mr. O. C. Hett are in charge of the exhibit.

The Canadian General Electric Company have an electric welding exhibit on view, which they are demonstrating to anyone interested. The machines are the direct current type operating at 60 volts.

The Dunlop Rubber Company, represented by J. R. Thompson, have a very effective display, consisting of a belt conveyor, elevator, and drive belt all in operation. The background of the booth represents a quarry in operation, showing the different uses to which rubber belting can be put in conveyor operations. They have also different types of rubber hose, and a full line of rubber goods.

The Allen General Supply Company, represented by Mr. Wilkes, are showing a number of power plant accessories designed to effect economy in fuel consumption. The well-known Venturi Feed Water Meter is the principal of these appliances, backed up by the Copes Boiler Feed Water Regulator, the Dwight CO_2 Indicator, and the Howell electric motor. In these days of high fuel costs, this exhibit should receive considerable attention.

The W. R. Sexton Boiler Setting Co. are displaying a full line of fire bricks, nonpareil grate bars and boiler settings. They have also a line of engine and pump packings, representing the William C. Wilson Co. in these lines. Mr. Sexton has charge of this exhibit.

The Canadian Hauck Burner Co., Ltd., are showing a number of their coal oil burners, which are in general use in foundry and shipyard work. Mr. Housel is in charge of the booth.

The Allen General Supply Company, represented by Mr. Wilkes, are showing a number of power plant accessories designed to effect economy in fuel consumption. The well-known Venturi Feed Water Meter is the principal of these appliances, backed up by the Copes Boiler Feed Water Regulator, the Dwight CO_2 Indicator, and the Howell electric motor. In these days of high fuel costs, this exhibit should receive considerable attention.

The Dunlop Rubber Company, represented by J. R. Thompson, have a very effective display, consisting of a belt conveyor, elevator, and drive belt all in operation. The background of the booth represents a quarry in operation, showing the different uses to which rubber belting can be put in conveyor operations. They have also different types of rubber hose, and a full line of rubber goods.

The Canadian General Electric Company have an electric welding exhibit on view, which they are demonstrating

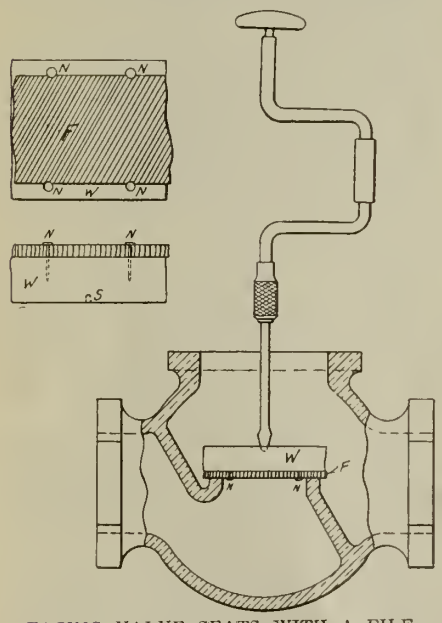
The Operators' Point of View

FACING VALVE SEATS WITH A BROKEN FILE

By David R. McNally

I have never seen this kink used and have been advised by several to submit it to POWER HOUSE. A quick and simple made rig for facing up a rough valve seat of the flat type can be easily made from a flat file.

"W" is a block of wood cut so as just to go in the opening in the bonnet connection of the valve. F is a piece of the best end of an old or new flat file



FACING VALVE SEATS WITH A FILE

broken to about the length of the block W. N are nails to hold the file into the block and driven far enough from the ends for the heads to just fit loosely inside the valve seat. This keeps it travelling in a true circle while it is turned with a brace and screwdriver bit.

A few turns will make a steam-tight job under ordinary circumstances, but in a bad case it will be necessary to clean the file grooves out when they fill and apply again.

ANCHOR BOLT DISCUSSION

Terrell Croft Replies

Mr. Hal B. Beecher, in his contribution, "Fastening Anchor Bolts," on page 349 of your August 5 issue, makes the statement:

"I wish to repeat: do not adopt Mr. Croft's plan, for it looks to me that a headless bolt set in cement might possibly be loosened into its bed if the bolts were subject to sharp and constant vibrations, which would have the same effect all through the bolt."

I fear that Mr. Beecher did not read carefully my contribution, "Anchoring Foundation Bolts in Concrete," to which he refers.

In my article appears this statement:

"However, as a matter of precaution, it is always well to use for a foundation bolt a rod threaded and having a nut on the lower end. On this nut a cast iron building washer or a square piece of wrought-iron plate can rest. . . ."

It was not the writer's intention to recommend the omission of anchor plates, where conditions are such that they can be installed. They should always be added as a precaution, inasmuch as the cost increase due thereto is very small.

Personally, I have never in my own experience known of an anchor bolt pulling out of a concrete foundation. Such happenings may have occurred, but I have never known of such and I have been more or less intimately connected with machinery foundation construction for the last fifteen years.

It sometimes occurs that it is impossible to, at reasonable cost, install an anchor plate and nut on the lower end of an anchor bolt. For example, in a number of cases it has been unavoidable that anchor bolts be set in an existing foundation at new locations. Where this is required, it is merely necessary to drill a hole in the foundation with an air drill, if such is available, or with a hand drill if it is not. The hole should preferably be one and one-half times or twice the diameter of the anchor bolt, which is to be inserted in it. The hole should be at least thirty diameters deep. Then, after the anchor bolt has been set centrally in the hole, a grout of one-half fine sand and one-half cement mixed to the consistency of thick cream is poured into it around the bolt, filling the hole. After setting a reasonable length of time, such a bolt becomes almost an integral part of the foundation mass.

A great number of anchor bolts installed as described above have been set for almost numberless sorts of services. Some of them have been subject to extra vibration. None, insofar as the writer is aware, has ever failed. Obviously, common sense dictates that an anchor bolt set as just described should be reasonably free from oil and should not be thickly coated with rust. If there is excessive oil on it, it should be wiped off.

If there is a rust scale on the bolt body, it should be scraped off. A corroded surface without scale, such as is acquired by any mild steel rod which has been exposed to the weather, will do no harm.

I would hesitate to assume the cost of Mr. Beecher's board and lodging during the period which would be required for him to loosen a bolt set as above "by tapping or striking said bolt for some time close to the cement, using a hammer or other tool." He might break the bolt off, but if it is properly set it could not be loosened so it could be pulled out.

About ten years ago the writer was connected with a company in New England that made some field tests on the resistance to withdrawal of plain unthreaded rod anchor bolts set in cement. An endeavor was made to withdraw, with a suitable appliance improvised for the experiment, from a concrete foundation, some bolts set by this method. In every case the bolts pulled asunder outside or near the top surface of the foundation. But in no case was it possible to pull one of the bolts out.

If any reader of POWER HOUSE knows of an instance, or instances, where anchor bolt set as above described have failed, I would like very much to have a record of the incident, inasmuch as I am interested in and make a specialty of machinery-foundation design.

To summarize, there should, if possible, always be an anchor plate, or, as Mr. Beecher suggests, a right-angle bend or hook at the lower end of every anchor bolt. But if conditions are such that it is impossible to provide the anchor plate or deformation, an anchor bolt may readily be so installed that it will not fail by withdrawal.

BOILING OUT A STEAM BOILER

When a boiler becomes heavily coated with scale through neglect or through long continuous use of very bad feed water, it is sometimes more convenient and safe to clean it by what is known as the "boiling out" process than any other method. Heavy scale diminishes the efficiency of any boiler, and if it is hard and compact it is less impermeable to the water than when of a porous nature, and neglecting to remove the scale at frequent intervals may damage the boiler by causing the metal to become overheated and burned.

Taking this into consideration it is advisable when a boiler is found to be

heavily scaled to immediately apply the "boiling out" process, although the time required may occasion considerable inconvenience in plants in which there is only one boiler. The "boiling out" process consists simply of filling the boiler with water to a point a little above the tubes or the upper limit of the scale deposit, and adding to the water a liberal amount of soda ash. Soda ash alone is usually sufficient, but in order to increase the efficiency of the treatment a small proportion of caustic soda may be added and both should be thoroughly disolved before being put into the boiler. With a slow fire and the man-hole left open the water should be kept boiling gently until the scale becomes loosened, when the water may be run out and most of the scale removed by means of convenient hard tools and by flushing out with a stream of water from a hose nozzle.

Particular care should be taken to remove all the scale possible from between the tubes and places difficult to reach, for the reason that when the boiler is restored to service, pieces of scale already loosened will fall down on the fire sheets and other heating surfaces which may result in overheating in spots.—"The Refrigerating World."

PUMP PROBLEMS

By J. E. McCormack

THERE is nothing new or original in the devices I am about to mention, but I have at one time and another made the acquaintance of pumps in various plants and in different counties, and the fact that none of them had been equipped as fully as I like to see a pump equipped leads one to bring up these subjects even if they are old. Only one pump had a foot valve, although this would be an aid in holding the priming when the pump was stopped. (Perhaps I should mention that at this writing I am not taking boiler feed pump into consideration at all). On those pumps which had piping for the suction line throughout, few of them had any more convenient means of priming the pump for a start than to take a cover off of the water end and pour water in. Two, or possibly three, had a tee at the highest point in the discharge line and through which water could be poured down on to the discharge valves, but, although an aid, water there is not nearly so effective on appreciable lifts as is water in the water cylinders themselves to prevent air passing the pistons, and especially to reduce possible air cushioning in the clearance and valve spaces, which said cushioning would expand again and follow the piston back on its return stroke instead of an unbalanced air pressure (suction) being produced to cause water to rise in the suction pipe. The amount of this possible cushioning depends on the degree to which the air must be compressed before it can escape through the discharge valves or other passage provided for it.

I like to have a foot valve on and a pipe connection from the discharge line or chamber to the suction chamber and a valve in this with which to make or break communication between at pleasure. With the valve shut, the pump works about the same as if this device was not on it, but in the event of the priming becoming lost and there being water in the discharge line the opening of this valve permits water to flow from the discharge line into the suction line and work up into the cylinders, the foot valve preventing its escape through the lower end of the said suction line. By this arrangement the pump can be quickly, easily, and effectively primed.

A suction chamber is a well-known device which can be constructed by means of a tee inserted in the suction line but close to the pump and into which a piece of pipe at least as large as the suction pipe (or hose connection) and two or three feet long is screwed and having a pipe cap on its upper end. The pipe constituting the suction chamber stands in an upright position. Although generally not necessary, yet, with a long suction line or a high lift, this device is an aid to prevent pounding when the pump reverses and also to enable the cylinders to fill with water at a high speed.

I think not more than four pumps had any means provided for letting the air (drawn from the suction line when starting the pump) escape, except through the pumps' discharge line. If but little pressure rests on the discharge valves this feature is of but little importance, but where an appreciable water pressure per square inch normally rests on the said discharge valves some way should be provided for allowing air to escape when starting and without requiring it to be forced through the discharge line. A bib cock or pet cock inserted in the bottom part of the air chamber, or even in the cover of the discharge chamber, is an aid, and sometimes a valuable one, though it still remains necessary to force the air through the discharge valves against whatever pressure is holding them down. With a foot valve on and the pipe connection I spoke of installed to, by means of a valve, allow water to flow from the discharge chamber or line into the suction line then the water pressure above and below the discharge valves becomes equalized with the valve open and the pump at rest and the air is therefore more easily sent through the discharge valves when the pump is started. The valve is closed before starting the pump or it may be left just a little open while the pump makes a few very slow strokes at first to exhaust the air, then entirely close the valve before allowing the pump to run up to normal speed. In a pump thus equipped, a bib cock in the foot of the air chamber will, when open, provide a short route escape for the air being displaced from the suction and the pump by the water admitted thereto from the discharge line.

Joints in the suction line should be as carefully fitted and as tight as similar joints would be made in a steam line, but if a joint there becomes leaky although at the same time well set up, a Yarway pipe clamp (formerly the Simplex) is as useful here as on a steam line, although I would not recommend one as a permanent remedy to be merely set up more from time to time as became necessary and without giving proper attention to the actual condition of the joint itself.

Strainer holes should aggregate five times the area of the suction pipe.

Put a globe valve in the discharge pipe to shut back the water in it when the water end of the pump needs repairing.

The longer the suction pipe, the larger it should be, and there should be a foot valve attached if the lift exceeds twelve or fifteen feet.

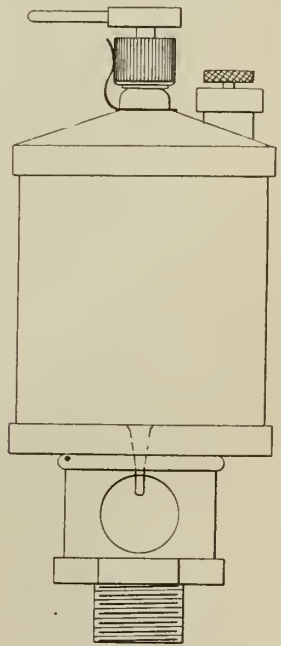
Lack of a suction chamber, or too small a suction line, will cause a pump to hammer in the water end. Squirting action may be lessened by increasing the suction valve area; by giving more suction chamber and more air chamber.

Pumps should be installed in such a position that there is room enough at both sides for working when making repairs and room enough at each end to admit of removing the piston rods if their removal should happen to become necessary later.

IMPROVING A LUBRICATOR

In a well-known type of air compressor lubricator in which the sight feed glass is of the disc or bullseye type, the feed nozzle terminates above the line of sight, so that before the drop can be seen it has broken away from the nozzle.

To make the drop visible while forming a strip of metal was soldered to the



FIXING THE LUBRICATOR

nozzle, bringing the point of the nozzle well into view.

The sketch will indicate what was done, the dotted lines indicating the nozzle as it was originally.

R. McLAREN.

BOOK REVIEWS

Analysis of Babbitt, by James Brakes, The Allen Book and Printing Co., Troy, N.Y.

It has been the desire of the author, as stated in his preface, to place before the mining, civil, electrical and mechanical engineer and others who have taken chemical analytical training, a small practical book on the analysis and manufacture of babbitt. The methods have been selected from the many methods in use for their simplicity, neatness and accuracy. At the same time reactions and data have been inserted which will prove interesting to the student in analytical chemistry. One of the most valuable features of the work is an extensive bibliography on books dealing with metallurgical engineering. The various metals met with in the manufacture of babbitt metal and similar alloys are each given a chapter to themselves and their properties, their qualitative, quantitative, volumetric, gravimetric and electrolytic analyses are taken up in detail. Each chapter closes with a biblography on the metal concerned. Antimony, tin, lead and copper are dealt with. Chapter five takes up the determination of magnesium and bismuth in babbitt, the qualitative analysis of babbitt and gives a bibliography on white metal analysis. Chapter six is devoted to notes on the manufacture of babbitt, examples of calculation, the sampling of babbitt metals and a bibliography of metallurgy. To the works chemist this book of 170 pages will prove an admirable aid where anti-friction metals, etc., are concerned.

"The Financier," London, Eng., has recently published An Empire Peace and Reconstruction number replete with commercial and other information relative to the British Dominions and Colonies. As might be expected, Canadian information is unusually complete, and the other dominions are also fully dealt with. Aside from the financial and other information contained in this number, much other data is found.

"Boiler Safety," a new booklet just off the presses of the Travelers' Indemnity Company, is a sister booklet to "Boiler Economy" recently issued by that company. Its purpose is to describe approved ways of preventing accidents in the boiler room. It is a convenient pocket size and will be a handy reference book for the engineer and fireman, as well as the plant owner.

In 175 pages the subject matter is divided up into forty sections, each of which relates to some particular phase of boiler room work, or to the care and operation of certain equipment or apparatus in the boiler room. Boiler explosions occur frequently, and many of them are enormously destructive to life and property. They are often caused by weakness due to improper design, inferior construction, or the use of unsuitable materials, but many of them on the other hand are plainly the direct results of careless or unintelligent operation of the boilers. In this booklet design, construction, and materials are not discussed. Emphasis is laid on the operation of the boilers.

The first section is headed "Putting Boilers in Service," and covers all the principal operations necessary to making sure that everything is in a safe and satisfactory condition for starting up. Among other important subjects treated are: cutting-in boilers, superheating, economizers, safety valves, blow-off valves, repairing boilers under pressure, laying up boilers, working inside of boilers, scale, water-hammer, mechanical draft, low water, and handling coal and ashes.

In short, "Boiler Safety" is a practical book for practical men. Its language is clear and concise, and although it covers its ground thoroughly and well, there are no formulas or theoretical discussions to discourage the man with a limited education. There are also thirty-two illustrations which show the results of boiler explosions, defective parts of boilers, approved power-plant equipment, and other subjects of interest to engineers.

As mentioned, the booklet is a companion volume to "Boiler Economy," which is now in its second edition, and for which there has been a constant demand since its first appearance in 1913. It is largely written by Allan D. Risteen (Ph. D. Yale), director of technical research of The Travelers.

CATALOGUES

The H. Mueller Mfg. Co., Sarnia, have issued a new catalogue (A) which shows evidence of considerable pains and expense in its preparation. This publication shows their complete line of brass plumbing products.

What Worried Jellico Most is the title of an interesting pamphlet issued by the Wheeler Condenser and Engineering Co., Carteret, N.J. This publication emphasizes the importance of good condenser tubes in naval, marine and land work, and tells the story of how the Wheeler Co. started the manufacture of their own tubes so as to be assured of their quality.

Guy S. Hamilton, advertising manager of the American Steam Conveyor Corportation, Chicago, has been appointed editor of the "Booster," the Corporation's newly-established sales organ.

S. F. Bowser and Co. have issued a folder illustrating and describing a Bowser battery oil storage system for lubricating oil. The folder can be arranged to show one outfit, two outfits, three outfits, or a battery of four tanks, so that a prospect may understand that as many units as desired can be purchased. The folder shows how units of various capacities line up in a uniform manner.

The Johns-Pratt Co., Hartford, Conn. cordially invites all members of the N.A.S.E., as well as all superintendents, master mechanics and operating engineers, to visit booths Nos. 221 and 222 during coming convention at Huntington.

THE RICHARDSON-PHENIX COMPANY ANNOUNCES NEW GENERAL MANAGER

Mr. L. E. Strothman, who, for several years, has been manager of the steam turbine and pumping engine departments of the Allis-Chalmers Manufacturing Company, left that firm on August 15th to become vice-president and general manager of the Richardson-Phenix Company, in which firm he has acquired a financial interest, Mr. J. Wm. Peterson becoming president and treasurer of this firm. Mr. Strothman is well-known in manufacturing circles, having been connected with the Allis-Chalmers Company since 1902, and prior to that with the Filer & Stowell Company and the Nordburg Manufacturing Company. As manager of the steam turbine and pumping engine departments of Allis-Chalmers, Mr. Strothman has gained an enviable reputation in national engineering circles. He is a member of the American Society of Mechanical Engineers, having held the chairmanship of the Milwaukee section during 1915 and 1916. In 1916 he was appointed associate member of the Naval Consulting Board by Josephus Daniels, Secretary of the Navy. Mr. Strothman is also a member of the American Society of Civil Engineers and the American Water Works Association.

MR. L. E. STROTHMAN.

NEW HOUSE ORGAN

Purdy, Mansell, Ltd., Toronto, have issued the first number of a new house organ, "The Sprinkler." While the title might indicate the subject of fire prevention by means of sprinkler systems, the subjects covered by their periodical will embrace the fields of power plant and heating and ventilation engineering as well. Sprinkler engineering is featured in this first number, typical illustrations being given of several installations recently completed by Purdy, Mansell, Ltd.

PEACE-TIME EXHIBITS

(Continued from page 403)

to anyone interested. The machines are the direct current type operating at 60 volts.

The Clemens Electrical Corporation of Canada, with headquarters in Hamilton, are showing their electrical soldering irons, and as these irons work at a voltage of 8 volts, the necessary transformers are also included in the exhibit. An interesting feature of the booth is the J. C. refillable fuse, a very neat and economical type of this largely used article. The booth is in charge of Mr. R. C. Guest.

Estimates Soon Ready.—Sir Adam Beck has assured the citizens of Galt through the mayor, that an estimate of the cost of the proposed Hydro Radial System in this district will be made by the new year. The municipalities will then be able to submit the by-law to the electors.

Paper Mill For Morristown.—The property owned by the Gillies Brothers at Morristown, directly opposite Brockville, who used the plant as their American depot, has been sold to representatives of Hearst, the American publisher. It is said that he will erect a mammoth paper mill on the site. Gillies Bros., who are large lumber mill men at Braeside, near Arnprior, formerly conducted a lumber business at Morristown, but closed down when lumber prices rose so high during the war.

Put your water wheel proposition up to us

Diamond Specialty Company literature has always been distinguished by its direct appeal to the engineering knowledge and sound business judgment of its readers. This is particularly true of Bulletin 132, "Profits That Get Away Through Your Boiler Room," just issued by the company. This bulletin, which is

an attractive, well-written book of twenty-four pages, deals first with the importance of exercising business-like supervision over the boiler room; the effect of soot on boiler efficiency; and in its concluding pages describes Diamond scot blowers for horizontal return tubular boilers. The book is well illustrated with charts, graphs and ledger sheets, showing actual improvements effected, and it should be in the hands of every operator of horizontal return tubular boilers. Copies may be had on application to the Windsor, Ont., office of the company.

To Buy Power.—The clerk of the York Township Council has been instructed to write to the Ontario Hydro-Electric Commission, requesting that negotiations be opened to purchase the lines of the Toronto Electric Light within the township. The council is preparing to extend the Hydro through the thickly settled districts, and with only one power company the expense could be lessened considerably.

New Power Company.—A Dominion charter has been obtained for the Wendigo Power Company, which has been capitalized at $1,000,000. The plant of the company will be twenty miles south of Larder Lake, and the head office at Guelph. Water powers on Wendigo Lake and the Blanche River will be developed.

Largest Airplane Engine.—The Sunbeam Works at Wolverhampton, England, have been recently testing what is said to be the largest airplane engine in the world. The engine is a twelve cylinder one, the cylinders being arranged diagonally. The horsepower expected to be developed is 900 at normal speed, and the weight per horsepower is less than two pounds.

The Matthews Engineering Co., Sandusky, Ohio, have issued an exceedingly attractive booklet on their fuel automatic lighting systems for private installation and use in suburban and farm homes. The effect of proper lighting and illumination upon civilization is treated of in the first portion of the publication and the actual generating sets in the remainder.

Colliery Loses Three Days.—Owing to a dispute over the employment of two men on the bankhead, a colliery of the Sydney Reserve mine has been idle for three days. The disagreement rose over the fact that two men had been employed to push the boxes on and off the scales, and the company thought that one should be sufficient. The men finally resumed work on the understanding that when production was increased sufficiently two men would again be employed.

Making Money From Moss.—The swamp lands in the vicinity of Brockville are to be used as money producers, the medium being the moss that is found in abundance thereon. Three carloads of this moss are being shipped to Rochester, N. Y., for use by nurserymen and florists, who wrap it around the roots of trees that are being shipped, and also in preserving cut flowers. The moss is sold by the cord and brings a good price.

New Industry for N.B.—The Hardwood Last Block factory, which was spoken of some time ago as about to be located at Mullin's Brook, York County, N.B., is now being built. The site is about four miles from McGiveny Junction on the Canadian National Railway. The interest behind the enterprise is H. Mobbs, of Kettering, England, said to be the largest maker of last blocks in the world. Between one and two hundred persons will be employed to begin with, and the manufacturers have entered into an agreement with the Nashwaak Pulp & Paper Company for 3,000,000 feet of hardwood lumber.

WM. B. SCAIFE & SONS CO. PITTSBURGH, PA.

The Canadian Mining Manual for 1918, edited by Reginald E. Hore. The Times Publishing Co., Toronto and Quebec.

This well-known annual has been enlarged considerably over former years and contains much new material of a statistical and mining nature about Canada's mineral wealth. In this new edition is to be found information concerning all minerals and metals produced in Canada, and all metallurgical and mining companies operating in Canada. Two chief objects have been achieved: to present in concise form matter of interest to persons connected with the industry, and to attract attention to the opportunities for the development of Canada's mineral resources.

The volume is exceptionally well illustrated with colored plates, half-tones and line cuts. A large number of mineral specimens are shown in natural size and color, these plates including some of the best reproductions of ore that have ever been printed. In the section of the book devoted to mine products useful information concerning the character, use and occurrence of each mineral treated. The minerals are dealt with in alphabetical order and the amount of space given to them varies. Owing to the great demand recently for information concerning certain minerals and metals special attention is given to war minerals such as magnesite, fluorite, pyrite, molybdenite, etc. A second large section of the book is devoted to mining and metallurgical companies operating in Canada. In each case is given the office address, the location of the property, and the name of the manager. In most cases capitalization, names of directors, officers, nature of operations, recent financial statement and record of production during the last year are given. These companies are treated of in alphabetical order.

Contents

Mineral production in Canada in 1917; Canada's water powers and their relation to the fuel situation; metals and metallurgical research; annual meeting of the Canadian Mining Institute; Alberta coal mines; the gold industry; the magnesite industry; fluorspar mining in Ontario; oil prospecting in Ontario; tungsten ore deposits in Manitoba; the Matachewan gold area; Molybdenite mining in Quebec; copper mining and refining in British Columbia; mining in Northern Manitoba; mining companies operating in Canada; mining companies listed according to product.

FIRED WITH POWDERED COAL

Powdered coal is to be used throughout for firing boilers and furnaces in the new sheet mill of the Falcon Steel Company now being erected at Niles, Ohio

The power plant boilers will be powdered coal fired, using the Quigley compressed air system for transporting and burning the coal. The pulverized coal will be transported from the milling plant through standard 4-inch diameter wrought pipes to furnaces and boilers for various distances aggregating approximately eight hundred feet, and will be switched from the main distribution line to a storage bin in the power house for use as required for the boilers. The contract for the complete equipment for preparing, distributing and burning the fuel has been awarded the Quigley Furnace Specialties Company, of New York.

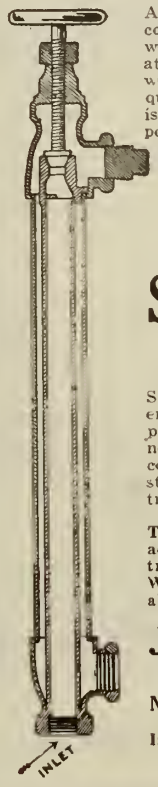
Large Power Drives is the title of a publication recently issued by the Morse Chain Co., Ithaca. This pamphlet deals, as the title indicates, with the chain drive in its application to large power transmissions of various types.

Electric Furnaces in the Iron and Steel Industry; Rodenhauser, Schoenawa and Vom Baur. John Wiley & Sons, Inc., New York.

This is the second English edition of this well-known work. In it a number of changes and additional matter have been incorporated consequent upon the rapid growth of the electric furnace industry. While a considerable number of books has been written on the subject of the electric furnace, the majority of them are of such general scope that the iron and steel industry does not receive the attention it warrants. An historical resume of the development of this branch is given and is followed by a chapter devoted to the explaining of the laws and principles of electricity which enter into electric furnace work. This chapter is somewhat elementary in its scope and has been inserted for the benefit of the general student interested in this branch of metallurgy. The effects of the electric current in the production of heat by resistance, arc or induction heating is dealt with next, together with other actions of the electric current in the furnace, such as the motor and pinch effects. Chapters IV, V and VI deal with power factor and alternating current theory in general, general conditions for the operation of electric furnaces and arc furnaces in general. The various types of arc furnace dealt with are the Stassano, now practically obsolete, the Heroult, the Girod and the Rennerfelt. Induction furnaces, now little used, are also treated of. Space is given to the electric shaft furnace for the reduction of iron ore. Part II takes up materials for furnace construction and the costs of operation, and Part III, the electro-metallurgy of iron and steel. These latter two parts of this book are of value from the economic standpoint as an exhaustive treatment is given of everything affecting the operation and economics of the electric furnace.

Fireman Scalded.—Through the blowing off of a cap on the boiler of the Smith Manufacturing Company, East Front Street, Toronto, a fireman was badly scalded about the face and arms. The man's name was John Smith, and he is 55 years old. He was removed to the St. Michael's Hospital.

Power House Economy



A Steam Trap that saves coal by abolishing heat-wasting steam leakage, and at the same time does its work efficiently without requiring constant attention, is the trap you want in your power plant.

The Long Patent Steam Trap Fills the Bill

Simple, reliable and efficient. Has but one moveable part. Automatic — requires no valves except those which control the admission of steam to apparatus to which trap is attached.

The Long Trap has several advantages over all other traps. Protected by patents. Write and let us tell you all about it.

NON-CORROSIVE CYLINDER OIL
MANUFACTURED ONLY BY
E. H. KELLOGG & CO.
NOS. 242 & 244 SOUTH ST. NEW YORK, U.S.A.
FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done — give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

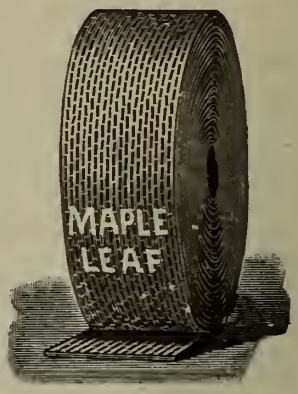
E. H. KELLOGG & CO.,
New York, U.S.A.

Dominion Belting Company, Limited
Hamilton, Canada

Sole manufacturers of the celebrated "MAPLE LEAF" Brand Stitched Cotton Duck Belting and Belt Dressing.

The demand for our products has steadily increased because the standard of quality has been maintained.

We make only one grade, the best that can be produced.



"MAPLE LEAF" is the strongest, truest running, most economical and efficient belt on the market for transmission of power, conveying, etc.

Being thoroughly waterproof it is suitable for running in wet or dry places. **"MAPLE LEAF"** Belt Dressing is different to others offered in that it is equally good for all kinds of belting, leather, rubber or Balata, as well as our own make.

Write us for prices, and if desired we will be pleased to furnish samples and further information.

A trial order will convince you of their utility.

Lexington, Mass.

Union Elbow. an economizer of the most pronounced type. Also made all female.

Male and Female Union. Takes the place of an all-female union and a nipple. Makes a short connection.

Union Tee. with union on the outlet. Made also with male end on outlet.

Clean Water Means Greater Boiler Efficiency

STATIONARY water screens which become clogged with trash, leaves and debris of various kinds, results in a dangerously low water supply to boilers, often making a complete shut-down of the entire plant necessary while clearing the intake.

Link-Belt Traveling Water Screens are self-cleaning. They need no attention whatever and insure a steady supply of clean water to boilers at all times. There are no expensive shut-downs, no extra cleaning costs, and no dangers to power plant equipment due to trashy water.

Send for a copy of our Water Screen Book.

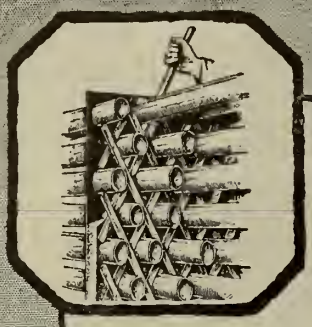
BETSON BAFFLES



VERTICAL, Any Slope for Any Make of Boiler

The solid one-piece baffle is the ideal baffle. It makes leakage of the valuable gases impossible. Ordinary baffles of separate brick or tile blocks have joints that cannot be made and kept tight. Betson baffles do away with these troublesome joints. The Plastic Fire Brick packs solidly in the tube spaces, and conforms exactly to the shape of the tubes.

HORIZONTAL, Any Shape for Old and New Boilers

Permanent one-piece baffles without joints, are easily made with Betson's Plastic Fire Brick. They do not crack under expansion, and are always gas-tight. Any one around the plant can do the job. No forms required. No special tools necessary. Betson baffles can be made in any size, shape or slope, for horizontal and vertical type boilers of any make.

Comes ready for use, in the yellow-top barrel.

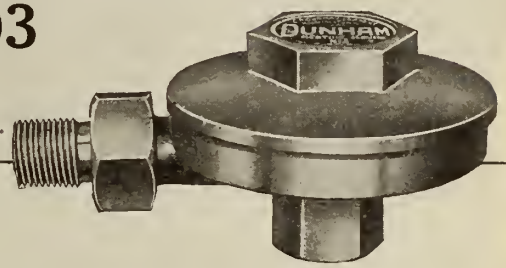
Same in principle to-day as in 1903



INVESTIGATE the trap question and you find two truths: that in the last fifteen years the carbon post type and the float type trap have been supplanted by the thermostatic disc type trap—and that the Dunham Radiator Trap, the *first* thermostatic disc trap, is essentially the same in principle to-day as when it was first marketed.

The Dunham Radiator Trap was designed to relieve the radiator of the entrained air and water under conditions varying from 10 pound pressure to 15 inches of vacuum, without adjustment. It did this in 1903—it does it to-day.

NORWALK AIR & GAS COMPRESSORS

Any Capacity **Any Pressure**

Used in Every State in the Union

Distinctive Features Which Add to Norwalk Compressor Efficiency

3. Head of Intercooler

In the Norwalk the intercoolers are placed **above** the gas cylinders. This permits of taking the gas out at the lowest point. Thus the intercooler is automatically drained and kept clear of any lubricant discharged from any cylinder or water coming from a chance leak.

Another advantage: the gas of lowest temperature seeks the bottom of the intercooler and is therefore first to be carried forward for the next stage of compression.

New bulletins on Air, Oxygen, Hydrogen, Acetylene and Carbonic Acid Gas are ready. Your copies on request.

The Canadian Who Bullied the Bolsheviks!

WHEN war broke out, Colonel "Klondyke" Boyle took across, at his own expense, 200 staunch Yukon volunteers. He was sent to Southern Russia, and in six weeks turned the transport system there from chaos into efficiency. He fed the starving Russian and Roumanian armies. He arranged temporary peace terms between Bolsheviks and Roumanians. Aided by twenty Chinese murderers and a brave Canadian girl, he bluffed the Bolsheviks and Austrians, in a tremendous exploit which won for him the title "Saviour of Roumania," and the personal thanks of the Roumanian royal family.

Read this story of "Klondyke" Boyle, by Arthur Beverley Baxter, in September MACLEAN'S—it starts on page 13.

"Growing Under Gouin"

—tells the amazing story of development of Quebec Province during the past fourteen years —in road-building, finances, industries and education.

"Meet Mr. Habitant"

—What does the rest of Canada know about the Habitant of to-day? Does he talk like Drummond's poems? This article, by Thomas M. Fraser, forcibly depicts the assets Canada has in French-Canadian stability and thrift, and will go far to remove any lingering prejudices which may exist in some minds.

Other Big Features

The Crowning of the King—By J. K. Munro, the pungent, pithy, political pundit.

Nuorteva's Propaganda—By C. H. Cahan, K.C., recently Director of Public Safety.

FOR ROCK CRUSHERS

LEBANON STONE CO.
Lebanon, Pa.

Magnolia Metal Co. 6/16/19.

Dear Sirs:—

Referring to your inquiry as to our experience with your MAGNOLIA BABBITT METAL would say that the writer has used this material exclusively for a number of years for general purposes, but more particularly, and in the largest quantity, for Pitman Bearings on an 18 x 36 Buchanan Crusher. This service is very severe and as these particular bearings are difficult to get to, we took care to see that we got a durable metal. To illustrate—One crusher we have been operating almost continuously for eight years, and during that period have found it necessary to babbitt the large Pitman Bearing only twice.

The above has been our experience, and from that we unhesitatingly recommend your metal.

Yours very truly,
T. MEAURON, Treasurer.

Pumps for any Service—Steam Appliances—Freight Elevators—Webster Vacuum Heating System.

NOTICE

TO

Stationary and Hoisting Engineers

Everyone operating a STATIONARY steam plant of 50 h.p. or over in the Province of Ontario must hold a Stationary Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Everyone operating a HOISTING steam plant working at a pressure of 20 pounds or over, irrespective of horse power, and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a Hoisting Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Application forms for obtaining STATIONARY or HOISTING Engineers' Certificates, may be had upon applying to the Chairman.

HON. F. G. MACDIARMID, Minister of Public Works and Highways. W. C. McGHIE, Chairman of Board.

W. A. RIDDELL, M. A; PH. D., Superintendent, Trades & Labour Branch.

When Buying Thermometers

There's Just Three Things to Remember—

First, you must have accuracy and sensitiveness—

Second, durability is absolutely essential—

Third, the thermometer must be suitably constructed for the intended application.

Accuracy, sensitiveness and durability are absolutely guaranteed in

"Crescent" Thermometers

And with nearly seventy years of experience to our credit, we are qualified to properly interpret your needs.

Our Catalog P.H. 200 illustrates and describes "Crescent" Thermometers for every application. Also test thermometers, glass thermometers, etc.

Get a copy of Catalog P.H.-200 to-day.

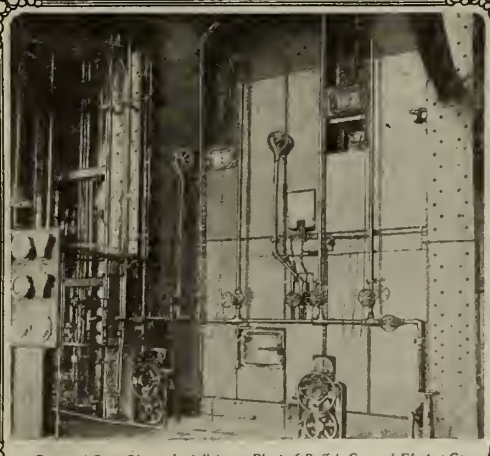
Diamond Soot Blowers on Edgemoor Boilers, plant of Aurora, Elgin & Chicago Ry., Batavia, Ill.



Diamond Soot Blower Installation—Plant of Buffalo General Electric Co

Standard in the Worlds Largest Power Plants

Visit the boiler rooms of the largest power plants in Canada, and you will find Diamond Soot Blowers in practically all.

Why?

Because Diamonds are essential to the cheap production of power. In no other way, than by their use, can clean heating surfaces be maintained. And clean heating surfaces in a boiler room mean increased ECONOMY, CAPACITY, SAFETY.

You will find Diamond Soot Blowers in the following representative power plants:

Canadian Kodak Company
Canadian Locomotive Company
Canadian Pacific Railway Company
Canadian Electro Products Company
Canadian Pulp & Paper Company
Ford Motor Company
Dominion Forge & Stamping Company
Western Electric Company
British Cordite Company
The Steel Company of Canada, Ltd.
Imperial Tobacco Company of Canada
The Canadian Salt Company
The Beaver Wood Fiber Company
Britannia Smelting & Refining Co.

There are hundreds of others. If the managers, superintendents and chief engineers of these plants consider Diamonds essential, there must be very substantial reasons why your boilers should likewise be equipped.

For full information ask for Bulletin 186

Power House

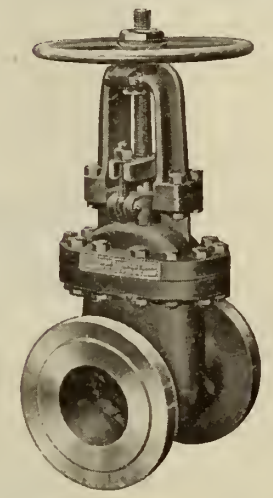
is a dominating factor in maintaining power plant efficiency in equipment and service

Every issue teems with advertising and editorial matter of a character that will keep YOU right up to the minute in power plant knowledge.

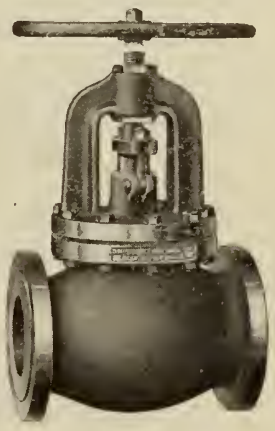
Two Issues per Month
Twenty-four per Year

And all for One Dollar

LUNKENHEIMER
Cast Steel Valves



Globe, Angle, Gate, Blow-off, Non-return Safety Boiler Stop, Pop Safety, Balanced Throttle Valves, etc.



For working steam pressures up to 350 lbs., and temperatures to 800°F.

These valves have long been recognized as the true standard of excellence for quality, efficiency and economy.

Their practical design, coupled with high quality material peculiarly fits them for high pressure superheated steam service, and the workmanship is of that high order which characterizes all Lunkenheimer Products.

The broad scope of the Lunkenheimer line of cast steel valves provides a type and size for every service requirement.

"Lunkenheimer - equipped" is synonymous for Safety, Service and Economy.

Specify **Lunkenheimer** and insist on having the genuine. Your local dealer can furnish them; if not, write us.

Scale in Your Boilers

Clean Tubes Mean Coal Saving

And easier firing, less ash-handling, fewer shut-downs, prevention of bagged or burned tubes, fewer repairs, and less frequent wash-outs. METLSKIN can pay for itself in a short time.

is an unprofitable boarder. Its appetite is enormous and it consumes far more than it is worth. Why not give it TWO MONTHS' NOTICE, and put an end to your loss thereafter?

THE SIXTY-DAY TEST OF METLSKIN is open to any reliable concern that is troubled with boiler-scale, pitting or corrosion. A small daily dose of METLSKIN, for a period of two months, will bring down the most tenacious scale, and absolutely convince you that A CLEAN BOILER IS NOT ONLY POSSIBLE, but EASY.

SEND A POSTCARD for the METLSKIN booklet and learn about Our Offer, Guarantee Bond, and Prices.

METLSKIN is neither "Compound" nor "Cure-all."

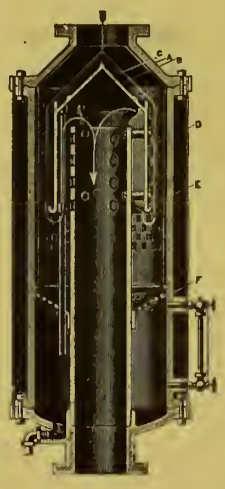
III IMPORTANT THINGS

TO CONSIDER ABOUT
A SEPARATOR



I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE—Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION—Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

Tuxeda
SWING JOINTS

Provide one of the easiest ways to save coal

Every pound of steam that escapes through a leaky connection represents a certain amount of coal wasted. Do you know that an average leak will waste 3,400 pounds of steam a month? Investigate your flexible steam connections at once and then investigate the Tuxeda Swing Joint.

A Guaranteed Solution for Your Flexible Connection Problems

Graton & Knight
Standardized Series
Leather Belting
Tanned by us for belting use

Triple Insurance

A Belt is a beast of burden that can spill a large part of its load without your eye perceiving it.

Here is a belt travelling at a speed of more than a mile a minute. It operates completely around the pulleys 70 times every 60 seconds. At more than a revolution per second, think how even little leaks would foot up a big total if this were not the proper belt for the work to be done.

All Graton & Knight Standardized Series Leather Belts give triple insurance against power leaks because, first, they are made of leather, the one belting material that has the right degree of elasticity to give and take up its tension, and the best of pulley-gripping qualities. Second, this leather is tanned in our own tannery, specifically for belting purposes. Third, our belts are graded into a Standardized Series which includes belts built specifically for every power transmission need Each is standardized in its manufacture and standardized for its work.

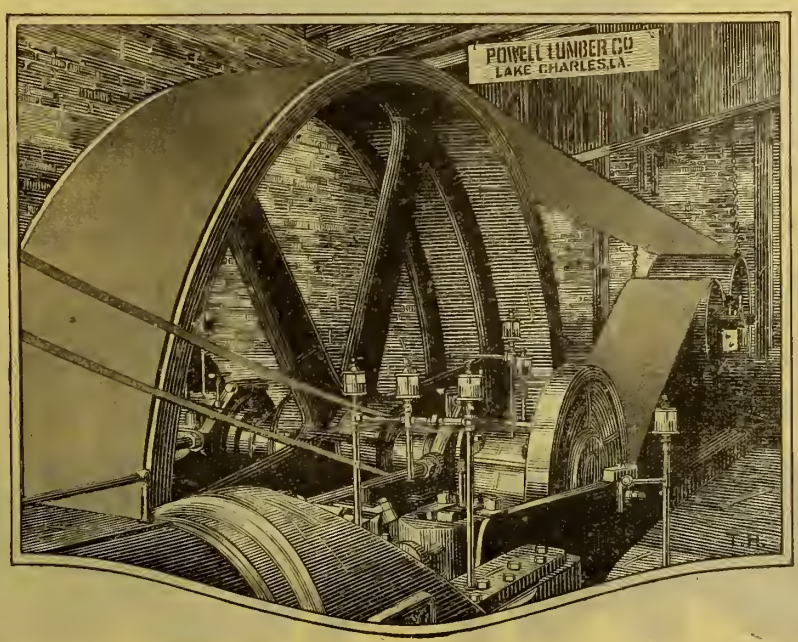
Selecting the proper belt and judging of its efficiency is not a job for guesswork or for the naked eye. It is a true engineering problem. Many of the best belted plants ask us to specify the belting for every pulley drive. Try the plan yourself. Then, when buying, call for "Graton & Knight——Brand or equal." This won't commit you to buying our belts. It will put your buying on the one basic consideration—the work to be done.

Write for Book, "Standardized Leather Belting"

CANADIAN GRATON & KNIGHT, LTD.
Montreal, Canada

Canadian Representatives: The Canadian Fairbanks-Morse Co., Ltd., St. John, Montreal, Ottawa, Toronto, Hamilton, Quebec, Calgary, Saskatoon, Vancouver, Windsor, Winnipeg, Victoria

By means of standardized methods of grading and manufacture, together with extensive investigations in our Engineering Laboratory, our Engineers are able to specify the correct belt for a given drive. Tests show that a 14 to 16 ounce belt should be rated at not more than 90% of the capacity of a 16 to 18 ounce belt. Consult our Engineering Department.



Here is a 34" Gra-Knight 3-ply Belt 82½ feet long. It was installed in December, 1915, in the plant of The Powell Lumber Co., Lake Charles, La. 14 ft. Drive Pulley, 136 R.P.M. 52" Driven Pulley. Belt Speed 5900 F. P. M. 443 horse power. The cost per horse power per week to date is 1 1/3 cents with several more years service to come.

50% More Heat

ALBERGER HEATER

You will avoid all expense and trouble common to ordinary heaters by giving your plant an Alberger Heater.

NO CORROSION, NO SPLIT TUBES, NO LEAKY HEADS, NO EXPANSION STRAINS

Alberger Heaters work fast, heating the water as fast as it is drawn. In fact it transmits 50% more heat than any straight tube heater.

Made in both horizontal and vertical types.

May we send descriptive bulletin?

THE small, corrugated, pure copper tubes in this Alberger Heater are expanded into **floating head** independent of the cast iron shell, which means that there cannot be trouble from expansion and contraction strain.

TRADE MARK REGISTERED

STRENGTH—GOODNESS—QUALITY

Etched on Every Glass

DURABLA HIGH PRESSURE GAUGE GLASS

Three years of experimental work have been necessary to develop and perfect an American glass possessing the elastic properties necessary to withstand sudden and radical changes of temperature and highest steam pressures, which will remain clear in any service.

Announcement is now made that DURABLA High Pressure Gauge Glasses, made in America, have passed every known test in actual service to determine the above qualities and are now ready for distribution.

DURABLA gauge glasses are carried in all regular sizes and are sold under the DURABLA guarantee.

For Rods

"Palmetto" Packing is braided round and square with a layer upon layer construction that gives it the great tensile strength necessary to long service under high pressure superheated steam and compressed air.

"PALMETTO"

Packing possesses the quality and perfect lubricant that insures the economy of long service. Let us send you free working samples to prove our claim.

For Valves

"Palmetto" Twist stands in a class by itself

Is ready for instant use, and any size valve may be packed from the spool by unstranding, each strand being a perfect packing in itself.

"Palmetto" Twist has great tensile strength, is heat-resisting and carries lubricant in each single strand.

PACK THE SMALL VALVES WITH "PALMETTO" TWIST

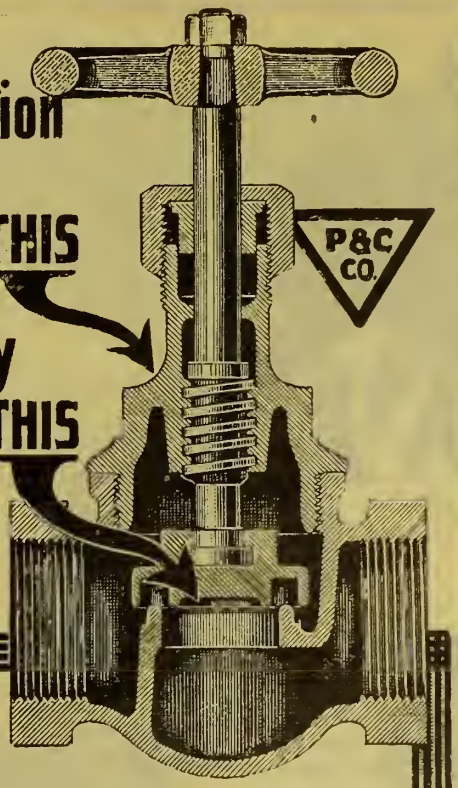
Conservation says SAVE THIS When only THIS is worn



If you believe in conservation you will believe in the Pratt & Cady Renewable Disc Globe Valve.

It is the valve of practical economy. The valve of common sense.

Instead of tossing the whole valve aside when the disc is worn down, you insert a new disc.

In this way you save the rest of the valve, which lasts indefinitely. The rugged construction of a Pratt & Cady Renewable Disc Globe Valve enables it to outlast many discs.

In the operation of renewal, which is quickly accomplished, the valve remains in the line. A saving of time and labor. Conservation at all points.

Thousands of these valves are in daily use by many industries, and they are all making good.

The economy of the Pratt & Cady Renewable Disc Globe Valve appeals to practical business men. Therefore we suggest that you

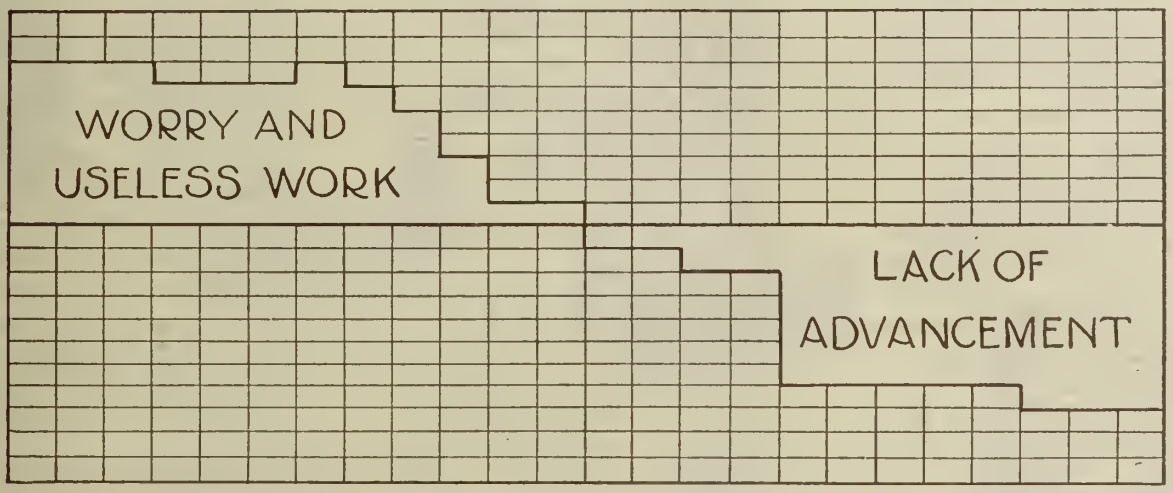
Let the C.A.S.E. Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

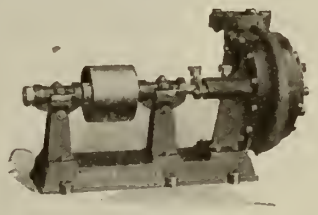
AMERICAN-MARSH PUMPS

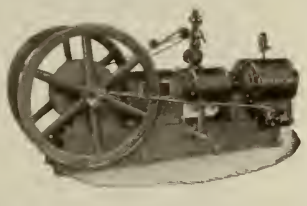
SIMPLE **RELIABLE** **EFFICIENT**

The American-Marsh steam pump is an improved form of the famous Marsh Pump which has been on the market for over thirty years, during which time over 150,000 have been manufactured and sold.

The American-Marsh Pump has no internal stuffing boxes, no tappets and no slide valves. The auxiliary valve is of the semi-rotative disc type of an improved design. The main steam valve is of the balanced piston pattern, assuring highest efficiency. The water ends have large valve areas and are fully bronze fitted, including solid bronze piston rods and bronze removable water cylinder bushings.



American-Marsh Centrifugal Pumps are made with the same high grade of material and workmanship which characterizes the construction of the steam pumps. They are made in all sizes up to 12 inch, both single and two stage for heads up to 250 feet.



The line also includes—

Power Pumps
Deep Well Engines
Air Compressors
Jet Condensers
Dry Vacuum Pumps
Boiler Feed Pumps

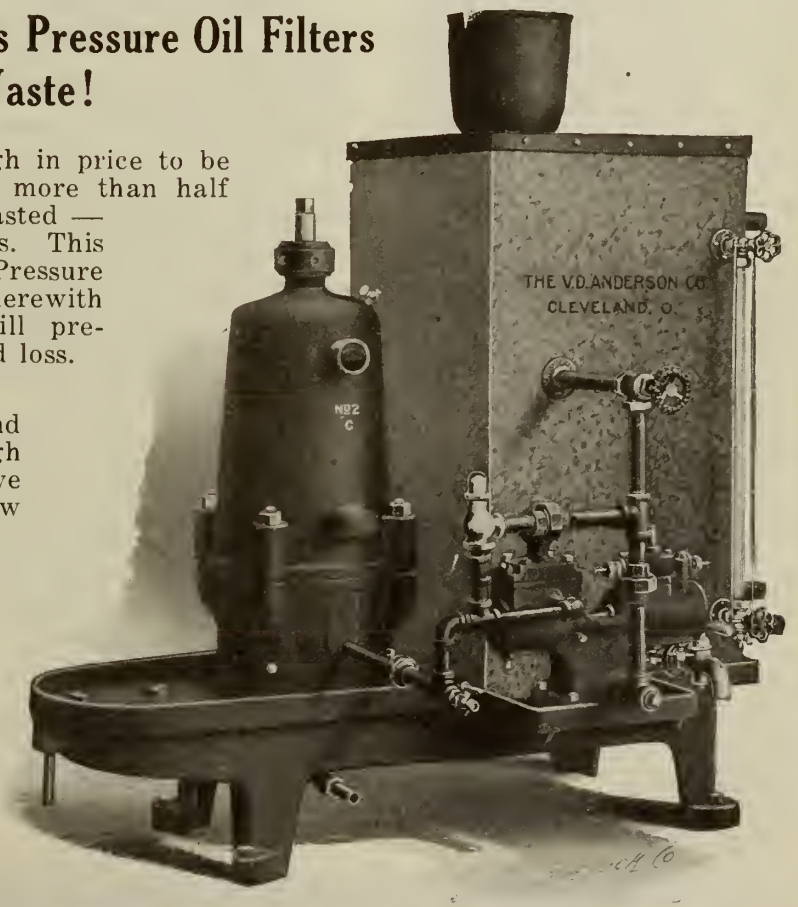
Why Waste Oil?

Anderson's Pressure Oil Filters Prevent Waste!

Oil is too high in price to be wasted. Yet more than half your oil is wasted — lost on wipers. This Anderson Pressure Oil Filter herewith illustrated will prevent this dead loss.



Place drip pans beneath engines and machinery. Then pass this oil through the **Anderson Filter** and you will have oil just as clean and as pure as the new oil you purchase.

You can use oil over and over again with the Anderson Filter. No other filter will do the work so thoroughly.

There are a few more points about the Anderson that we would like to take up with you. Pleased to have you drop us a line.

It's Easy To Save Oils The BOWSER Way

ESTABLISHED 1885

Bowser Oil Storage Systems make the handling of oils so easy, so systematic and accurate that immense savings in oils are made compared with the "barrel, steel drum and spigot" method.

Workmen take pride in operating Bowser equipment because it lightens the work, helps them keep a cleaner shop and enables them to make a far better showing for their department.

Oils Are Handled Mechanically

Receipts, storage and deliveries are accurately measured, checked and may be recorded. There is no over-running of measures, no loss of expensive oils, no mussy, oily, waste-littered floor, to invite fire or disaster. Insurance authorities commend the use of Bowser Oil Storage Equipment.

We will be glad to make a survey of your plant, outlining equipment suitable for your requirements. Write us today for literature

DEFENDER

DUPLEX DRAFT GAUGE

The Peer of Them All

Price $20.00

They read: Draft over the fire. Draft at the last pass of the Boiler and the differential through the Boiler.

THE FIREMEN CONTROL the fires by the readings on the Gauge. It shows every condition of the Fires and Boilers, except Flue Gas Temperatures and the Defender Flue Gas Pyrometers show the Flue Gas Temperatures. Also see the Defender CO_2 Analysers, put up in permanent case so as to take a reading for CO_2 in less than one minute's time. Write for Bulletin No. 100.

Defender Catalogue No. 11 shows the largest assortment of Combustion appliances, efficiency instruments and damper regulators made. We can help you save fuel.

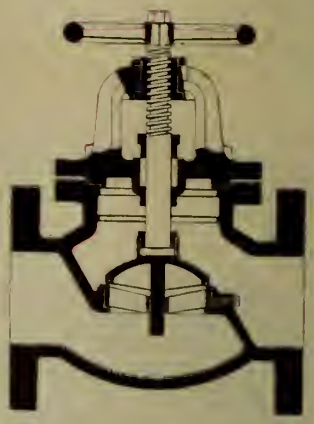
Imitations Speak Loudly for Beaver Valves



A WARNING TO THE TRADE. The James Morrison Brass Manufacturing Company, Limited, were the original designers and manufacturers of Beaver Valves. These valves have, during the eight years they have been on the market, gained such a reputation for service that specifications usually read "Beaver or Equal."

This has led to imitations of this Valve being placed on the Market

The design is not everything in Beaver Valves, the utmost care being taken in the quality of metal and the process of manufacture.

Buy the GENUINE Beaver Brand

The valve with the eight years' reputation

and Guarantee Your Plant

The Genuine Beaver Valve Service.

May we send our Descriptive Booklet

The James Morrison Brass Mfg. Company, Limited

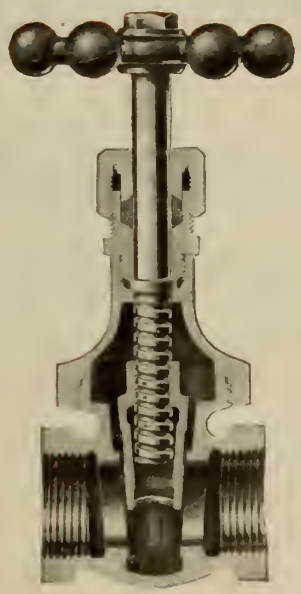
PENBERTHY

BRASS VALVES



PENBERTHY

BRASS VALVES

COMPODISK

WITH THE COMPOSITION DISC
Registered for
175 lbs. steam pressure.

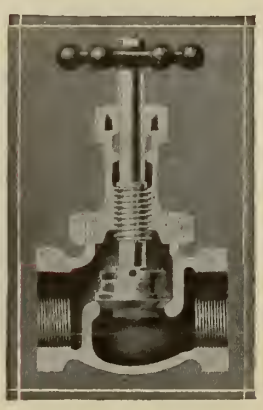
"The Gate that's up-to-date"

SOLID WEDGE GATE NON-RISING SPINDLE
BEST QUALITY METAL
Registered in Ontario for 150 lbs. steam pressure.

"The Outside Bonnet Construction"
protects you from injuries that may result from a loose fitting and unsafe bonnet
it prevents corrosion of threads because they are on the outside away from action of steam, water, etc.
it allows the valve to be taken apart easily and quickly without strain or injury to any part.
Doesn't this valve appeal to your own good judgment?

MADE IN CANADA

REGRINDING



WITH THE METAL DISC
Registered for
200 lbs. steam pressure.

The Penberthy Line of Valves

represents the most modern and progressive ideas of valve construction. The "outside bonnet" is without doubt the most sensible, practical and reliable improvement ever made in valve construction during the past fifty years.

"Penberthy Means Progress in Valve Construction"

Hose was hose — Till Goodyear Built it

THE GOODYEAR CORD TIRE of to-day would not have been possible had Goodyear been guided by the hide-bound traditions of the rubber industry.

Nor could Goodyear Industrial Hose ever have reached its high degree of perfection.

But Goodyear refused to be bound by precedent or trade prejudices. Hose fit to meet modern industry's varied and severe demands was our goal. Prevailing methods of construction would not do. Better methods had to be developed.

It was typical of Goodyear to study the hose requirements of industry exhaustively—to want to know exactly the conditions industrial hose must meet in use.

To discard existing processes of hose building, rubber compounds and cotton specifications and set new and more exacting standards—to develop more modern processes and methods of construction.

So you are offered the more efficient Goodyear Industrial Hose—hose that embodies all the virtues demanded by the strenuous needs of 20th century industrial life.

For foundry, paper mill, mine, railway, steel plant and every other industry there is a Goodyear Hose that will meet your needs more exactingly; that will give more lasting service.

Goodyear Industrial Hose will open up to you new possibilities of economy, increased production and hose satisfaction

A man trained by Goodyear in hose problems will gladly call upon you without obligation.

Just phone, wire or write the nearest branch

Genuine British Oak Tanned

Leather Belting

Only flawless backs are used and our Genuine British Oak Tanning process preserves all the hide's natural strength. Minimum Stretch, minimum slippage, and few breaks are characteristics of belting made in this way.

May we put you in touch with some users in your district?

We'd like you to profit by the experience of others.

"Engineers who know" always speak highly of our product, and do not hesitate to recommend it.

Many of Canada's largest power plants have been using it for years and years.

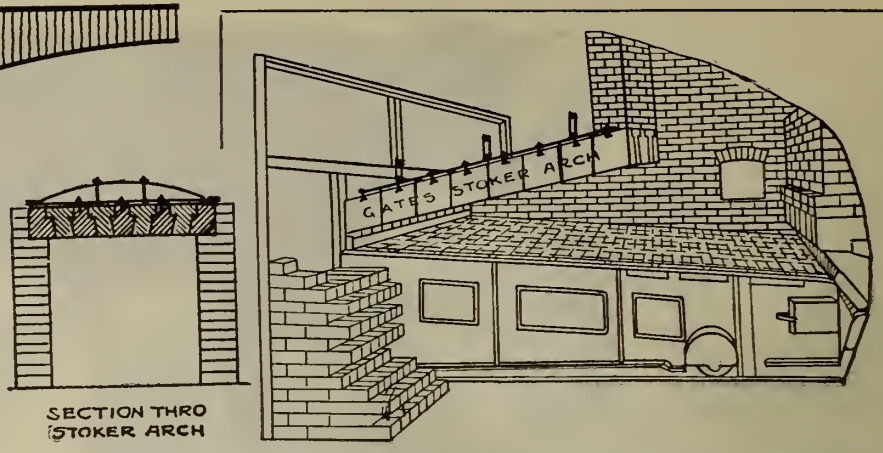
GATES STOKER ARCH



BUILT on the unit principle, any section of the arch can be placed without disturbing the rest of the brick work. Saves both time and money in making repairs — and frequently saves expensive shutdowns.

THE Gates Stoker Arch minimizes stoker arch maintenance cost.

Our new type of arch block is adapted to Dutch oven type of boiler setting, or H.R.T. boiler back arches, large fire door arches, reverberatory and smelting furnaces as well as stoker arches.

If your setting is not standard we will design a block to suit your requirements.

We specialize in all kinds of POWER PLANT BRICK WORK.

Call on our engineers at any time for information you may require. Their services are offered to you without obligation.

GATES REFRACTORIES LIMITED, 382 St. James Street, Montreal

Hoyt Babbitts Cut Costs

Lighten Friction Load — Save Wear and Tear

You believe in operating your power plant economically? Then see that your babbitting metal is of good quality. You can rely on **Hoyt's Frost King** and **Hoyt's Nickel Genuine** to cut the costs. They have the quality that promotes smooth running of machinery, lightens the friction load and saves wear and tear on belting.

Hoyt's Frost King

This general purpose babbitt has won its way into many of the foremost power plants of the world. It represents 40 years of success and has won the favor of Canadian engineers from coast to coast.

Hoyt's Nickel Genuine

This famous babbitt is recommended for use in gas engines, gasoline engines and all classes of marine engines. Especially adapted for automobiles. There is no better babbitt made for high-speed work.

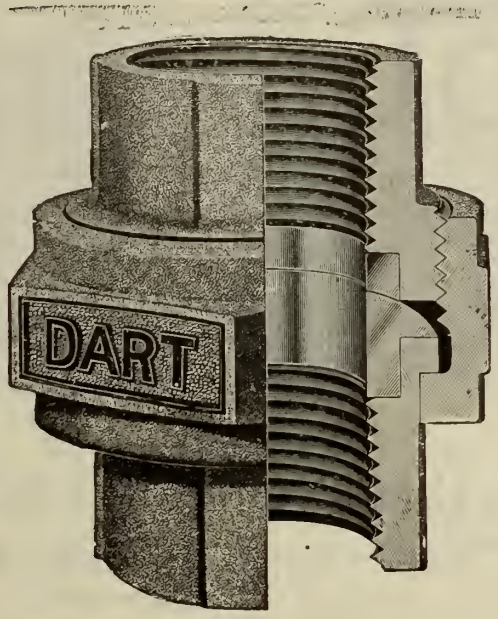
DART

Bronze Face and Seat



Heavy Iron Parts

The Union Pipe Coupling
That Never Springs a Leak

WHEN connecting up your steam, water or air systems make it safety first and use Dart Unions.

Dart Unions are invaluable because of their remarkable performance. Once installed there is no need for further thought. No upkeep cost. No replacement cost. No loss from leaks.

DART
TRADE MARK

DART
TRADE MARK

Dart Unions Stay Tight because the non-deteriorating **Bronze Face** and **Seat** are supported by iron parts of unusual strength.

Ball-shaped Seat allows perfect connection regardless of alignment.

Dart Unions can be used over and over again. They're always right. Your jobber sells them.

Manufactured by

DART UNION CO. Limited
TORONTO, CANADA.

They require no brickwork
They burn cheap fuel

They take up only one-seventh the space of the ordinary boiler.

The above are some of the advantages of using the

TALBOT
CONTRA-FLOW
Steam Boilers

Boilers of the water-tube type, quick steaming without any large steam or water spaces, making serious explosions impossible. Automatic water and oil control. Tubes easily replaced under reduced steam pressure.

Built in all sizes from 50 to 4,000 H.P.

How the Discharge Pipe is Water-Jacketed for Final Cooling of the Air or Gas as it Leaves the Compressor.

NORWALK AIR & GAS COMPRESSORS

Distinctive Features of Norwalk Compressors

5---Water-Jacketed Discharge Pipe

Norwalk water-jackets are distinctive. The jacket around each compression cylinder is constructed by drawing in a close grain metal banding to the outside shell of the cylinder, the space required for water circulation being left. Thus the jackets are not formed in the casting as ordinary practice allows.

The Norwalk cooling system also embraces a water-jacket around the final discharge pipe. This insures that the air or gas will be discharged at a low temperature for maximum efficiency.

New bulletins on Air, Oxygen, Hydrogen, Acetylene and Carbonic Acid Gas are ready. *Your copies on request.*

The NORWALK IRON WORKS COMPANY
SOUTH NORWALK, CONN.

Pioneer Builders of Compressors

Design and Construction — Article No. 1

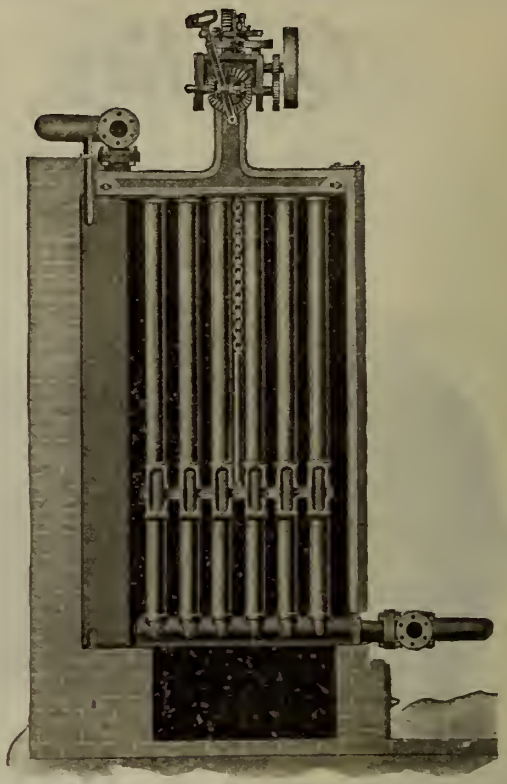
General:—

GREEN'S ECONOMISERS

consist of a series of sections, each composed of from 4 to 12 cast iron tubes varying in length from 9 to 12 feet. The tubes are fitted into top and bottom headers which are in turn connected by top and bottom branch pipes. The exterior of the tubes is easily kept clean from soot by self-aligning scrapers running slowly up and down the tubes. The economiser is usually enclosed by a brick wall on one side and sectional covers on the other.

Feed water enters through bottom branch pipe and leaves by the top branch pipe. The waste gases of combustion pass through the economiser at right angles to the sections, thereby heating the slowly circulating water in the economiser and reclaiming large quantities of heat which would otherwise be wasted.

The remainder of this series will be devoted to describing separately the design of the major parts of the economiser.



GREEN'S ECONOMISER, LIMITED.
TORONTO

The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.**
BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.

Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

Steady, Dependable Power

INDUSTRIAL success is based on power—steady, dependable power. Every mechanical unit in your plant—engines, dynamos and machines—must give 100% efficiency and therefore must be carefully and properly lubricated with lubricants of correct body.

When choosing your lubricants, you cannot afford to consider any factor other than quality. Good lubricants, like those in the Imperial line, are always most economical. They cost less per lubricating hour because they last longer; they do not wear or burn out as do poor lubricants.

Imperial Lubricants are right. They never vary in quality and will give you continuous satisfaction and better dollar-for-dollar value. They are made only from the best crudes obtainable and are as perfect as science and experience can make them.

Look over the list on the left. Among those lubricants you will find the right lubricant for every moving part of every machine in your plant. Their use will enable your plant to give steady, dependable power under every service condition.

We invite you to consult with our Lubrication Engineers. Their advice or assistance is yours for the asking. Address us at 56 Church Street, Toronto, or at any of our branches.

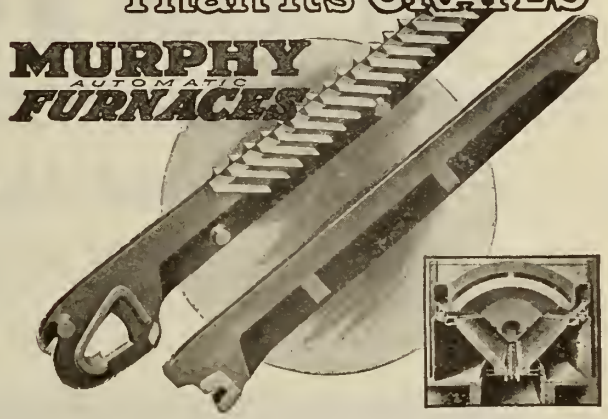
Turbine Undergrate Blowers, Centrifugal Blowers and Exhausters, Small Power Turbines, Damper Regulators and Grates

We make them Safe—
We make them Strong

No Stoker is Better Than its GRATES



Back of every feature of MURPHY GRATE construction are *many* sound reasons. Consider how these features save you dollars—in fuel—in labor—in maintenance.

The long—narrow—but deep sections give eighteen to twenty-eight square inches of cooling surface to every inch of exposed grate surface.

The liberal air space (47% to 52%) gives double the capacity of the boiler "without one penny for draft."

The correct proportion and distribution of ribs on the stationary grates, combined with the greatest accuracy of machine moulding have solved the sifting problem.

The continuous movement of the ribless grates ¾" above and ¾" below the surface of the stationary grates—breaks up the fuel bed—prevents avalanching—keeps the grates clinker-free—and advances the ash gradually to a point where it is removed by the clinker grinder. It is this action that gives the Murphy Furnace the faculty of *burning anything that has heat in it.*

Yet with all these advantages, the Murphy Grate of to-day is built to the same policy that has characterized every improvement: First, to make all parts standard; second, to make every piece interchangeable; third, to advise users of new developments so that they may keep their equipment up to date—and operating at top notch efficiency.

For information on the Riley Underfeed Stokers for large boilers, see September 5 advertisement or send for Riley Stoker catalog H R-10.

POWER HOUSE

Established 1907 — Published Semi-monthly

Construction of The Ljungstrom Steam Turbine

This Turbine is Unique in Its Design, Permitting as It Does of a Radial Flow of Steam Through the Blades From the Shaft Outwards

THE accompanying illustrations and drawings show the Ljungstroms Angturbine of Finspong, Sweden. This Swedish steam turbine of the reaction type suffers from certain drawbacks, some of which are shared by impulse machines and others are peculiar to itself.

It is stated that to get high efficiency at practical blade speed involves a very large number of blade rows, and consequently a long and expensive rotor. With a high or rapidly varying superheat, there is always a risk of distortion of the casing, which may result in the stripping of the blades, while the necessary normal temperature gradient down the casing combined with the effect of heavy joint flange and equalizing pipes also brings expansion troubles and the necessity of providing for ample clearances. This limits the possibility of economically utilizing high pressure and high superheated steam. This has led to the adoption in certain cases of a combination of reciprocating engines and turbines which would otherwise be unnecessary.

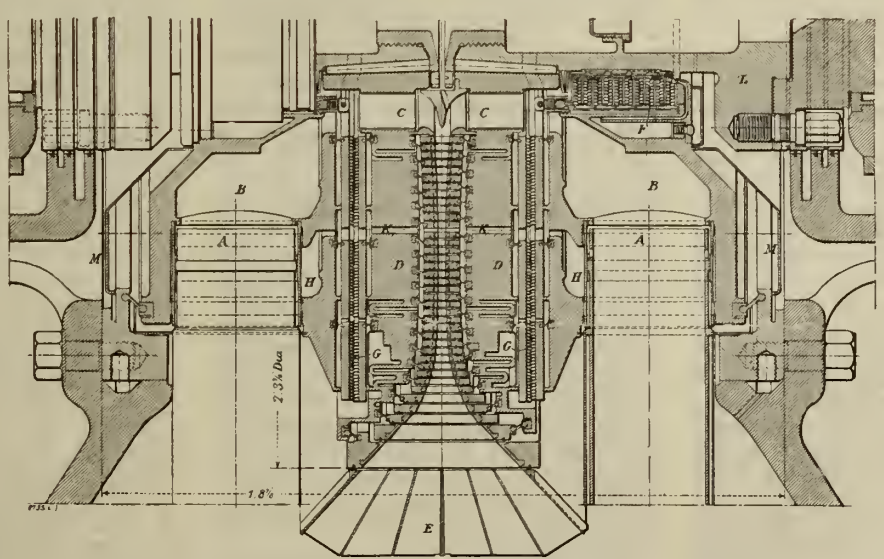
Mr. Birger Ljungstrom, a Swedish engineer at Stockholm, designed this reaction turbine in which certain drawbacks to the usual type are avoided. He was assisted by his brother, Mr. Frederick Ljungstrom, producing a machine of an undoubtedly remarkable character. The Ljungstrom turbine is a radial flow reaction turbine, the steam being admitted between two discs, and in its passage from their centre to their circumference passing between concentric blading rings, carried alternately by the two discs. In the usual design both of the discs revolve, driving their shafts at equal speeds, but in opposite directions, and to each shaft is coupled an electric generator.

The relative speeds of each set of blades is thus twice as great as in a standard reaction turbine of equal revolutions and diameter, and thus for equal efficiency the total number of blade rows is only one-quarter as great. Moreover, as there is no split cast-iron carrying blades or dummy packings the whole of these parts being mounted on the solid circular discs, the fear of distortion troubles is completely eliminated. The inventor has made provision for the highest superheat it is practicable to use, and disc design provides a very small turbine for the power developed, and although two generators are required, the overall size of the complete unit is materially less than that of an ordinary reaction turbo-generator of corresponding power.

At Liljeholmen, Sweden, the first turbine was built, which was so promising that a machine of practically identical design, but of 1,000 k.w. capacity, and complete with electric generators, thoroughly tested and constructed, and gave excellent results. The 800 kw. steam turbine is in the centre, with an alternator on each side of it, and at the end of one of the alternator shafts is mounted a small exciter for the fields of both machines. The lower half of the turbine casing is formed into an exhaust branch, which is bolted direct to the condenser heat, without the intervention of any expansion joint or similar device.

The exhaust branch is the only rigid support the turbo generator possesses, so that the latter is as free as possible from any strain due to its attachments. There are springs contained in cast iron boxes beneath each generator which support the weight of these and prevent strains due to their overhang. It is intended to carry everything on the condenser alone, so that no foundations whatever are required except those for the condenser and auxiliary machinery. This, of course, is great practical convenience, apart altogether from the elimination of strains in the turbo generator.

There are two hand wheels on the upper part of the turbine casing, which admit extra steam from overloads, and allow for hand adjustment of operation under the feet of each generator are the spring boxes, while outside these again are the rectangular air ducts for the generators, descending through the floor. The air enters by these ducts, and, after traversing the generators, escapes through the orifices on top of the turbine casings. Each generator has its independent air service and its own tachometer. The rectangular box underneath the exciter contains the oil pump and cooler, and the governor is between the exciter and tachometer dial. There is the shield of the end alternator, and attached to the bearing a steel cable, traversing the outside of the exhaust branch



CROSS-SECTION THROUGH LJUNGSTROM STEAM TURBINE.

in a sloping direction, and this cable is under tension, holding shut an oil relief valve in the relay actuating the stop-valve. The cable can be released either automatically by the melting of a very fusible metal plug in any of the bearings, or at will by a small lever at the stop valve.

In case it should break, get loose, or be released by the overheating of any bearing, the turbine is automatically shut down and there is an excess speed safety device on each alternator shaft, which also acts by releasing the cable and thus relieving the oil pressure. The 1,000 kw. steam turbine operates at 3,000 revolutions per minute and has an overall length of not more than 17 ft., 4 11-16 in., the greatest diameter being side discs fit in turned seatings in the of the governor only about 5 ft., 6 in.

The turbine is surrounded by exhaust space and there is no need for lagging of any kind upon the surface of the casing, which never exceeds the condenser temperature, and this not only minimizes radiation losses and permits of ready access to the bolts, but conduces to a pleasant temperature in the neighborhood of the machine.

The steam, after leaving the stop valve, enters the casing by a pipe passing through the side of the exhaust branch, where it branches off and ascends to the turbine by means of two vertical pipes, which are of steel. Radiation from them is minimized by jackets of thin steel, enclosing an air space, and the branched pipe is made by welding, the jackets being also welded on.

It will be noted that they are turned down on the outside, leaving a shallow collar about ½ in. wide near the end, this collar being a tight fit into a thin steel brush firmly fixed into the cast steel side discs of the turbine. These side discs fit in turned seatings in the casing, and serve to locate the turbine. When the turbine is removed it is lifted off the ends of the branch pipes.

Except around the collar there is no contact between the pipe and the bush, but steam freely circulates between them. The steam from each pipe enters an annular chamber in the side discs, whence it passes by means of a number of large holes to the space between the turbine discs. The opposing faces between the turbine discs carry rings of blading, supported from the discs by means of conical rings of bull-headed section.

When the steam leaves the last blade-ring it enters a diffuser comprising a number of diverging channels in which the residual steam velocity is re-converted into pressure, and the vacuum at the blade edges thus lightly increased above that maintained in the condenser. It is of interest to note that this diffuser is built up of sheet steel by welding, and is mounted on suitable supports in the turbine casing, and it comes away with the turbine when the latter is removed. In such a turbine steam packings have to be provided both to prevent the steam escaping along the shafts where the latter pass through the side discs and also to prevent it escaping freely up the back of the running discs, and thus uselessly into the condenser.

This packing has to fulfil another function constituting a balancing device to neutralize the pressure of the working steam, tending to force the discs apart. When the turbine is required to take an overload steam is admitted to the annular chambers, by means of either or both of the overload valves on the casing, which allows it to pass through the turbine discs.

Each turbine shaft is hollow and carries the running part of the packing and the turbine discs. The packing is mounted on solid feathers, and held in position against a collar by the turbine disc between which and the packing are two concave spring washers. The disc is keyed to the shaft by a number of taper pins, and is held from coming off by a flanged spigot screwed into the end of the shaft. The turbine shafts themselves have no bearings, but are registered and fastened with set screws each to its own generator shaft, the bearings belonging to the latter. There is, however, very little overhang as each turbine shaft is only about 10½ feet long.

The weight of the two running discs, complete with blading, being only 265 lbs. and 303 lbs. respectively, no difficulty is experienced in securing true running. It is of interest to note the small dimensions of the turbine, namely 27¾ in. diameter by 20⅞ in. long. Extreme care has been taken at every point to minimize heat losses and to avoid possible trouble from the very high superheats for which the turbine is designed.

It may be mentioned that the only external parts of the turbine which are heated by live steam are the small surfaces of the side discs and these are lagged and cased with sheet metal. Every part is circular and without flanges or horizontal joints. The packings, dummies, turbine discs and blading system are all of nickel steel, and wherever there is either a gradual or an abrupt temperature gradient steps are taken to provide against distortion. This is particularly noticeable in the formation of the turbine discs, which are nearly cut through in places by deep annular grooves, to avoid the distortion which would inevitably otherwise occur in thick discs highly heated at the centre and comparatively cool at the circumference, against distortion, there is a system of conical rings forming a connection between parts which are liable to be momentarily or permanently of different temperature and the side discs, which are hot, are held to their supporting rings, which are cold, by this device. The two sets of the dummy discs are similarly supported, one to a facing on its side disc and the other to the back of its turbine disc.

Every individual blade-ring is fixed to one or other of the turbine discs by the same method of attachment. How these rings are made and fixed will be described in conjunction with the blading.

The blading of the Liungstrom turbine consists of a number of concentric blade rings carried alternately by the two turbine discs. It will be seen that in the 1,000 kw. turbine there are altogether thirty-eight rings, the blades being of the Parsons pattern. From the centre the first 33 rows are 5 mm. wide, the next 2 are 7 mm. wide, and the last 2 12 mm. and 20 mm. wide respectively. The blading is first made in lengths of about 3 ft., being milled from the solid round bar of nickel steel. This is done on an ordinary horizontal milling machine, having four formed cutters mounted on its spindle. The first cutter roughs out the convex side of the blade, the next finishes this side, and the third and fourth respectively rough out and finish the hollow side, while the blade strip is extremely well finished when it leaves the machine. Still it is polished to a mirror-like surface, both inside and out, before it is built into the rings. Polishing is effected by the use of a simple machine using a tape band about 2½ in. wide, treated with polishing paste.

The discs, which are of soft iron, are mounted on a mandrel and their edges turned, inside and out, to the proper contour, and they are then dismounted and punched to receive the ends of the blading, a second punching process nicking the inner faces of the discs in such a way as to form registers for holding the blades to the exact angle. When the punching is done, the discs are reassembled on the mandrel with the blades in proper position. The mandrel is then held vertically and the rim of the disc and projecting blade roots are welded up solid together by melting iron wire into the groove by the aid of an oxy-acetylene blow lamp. Both ends of the blades having been welded into the discs by this process, which is neither difficult nor particularly slow, the mandrel is again put in the lathe and the discs and welded part are turned down and the ring parted.

The ring then consists of band blades with homogeneous root rings at each end, the latter having a small and slightly dovetailed mate register formed on the outer faces of the proportions. The very small pitch of the blades, as compared with standard practice, is also noticeable, the pitch sometimes being less than ⅛ in. The discs on the mandrel are ready to have their edges again turned to form rings of smaller diameter. Strengthening rings are next to be fixed to each end of the blade ring. These strengthening rings are made of spring steel containing 6 per cent. of carbon.

The strengthening ring is first formed on the circumference of a disc, and before it is parted off its side faces are machined. While the disc is still in the lathe the dovetail on the blade ring is entered into the groove on the face of the strengthening ring, and the edges of the latter squeezed in, so as to grip the dovetail tightly. To effect this, a simple device, consisting essentially of a pair of hinged arms, having rollers at their ends, is carried by the tool rest of the lathe. The arms embrace the ring and the rollers are brought towards each other to bear against the inside and outside of the dovetail joint by means of a screw.

When the lathe is started and pressure maintained on the rollers, the edges of the groove are rapidly and firmly closed upon the dovetail and to all intents. The outboard strengthening ring is the first to be formed, and when the blade ring is secured to it the composite ring is then parted off. The other strengthening ring is then formed, and after having the composite ring inserted and fixed, this also is parted from its disc.

There is then completed a blade ring but for the fine radial fins on the exterior circumference which are provided for afterwards. The conical, double bulb-headed ring connecting the blade ring to the turbine disc is turned from the edge of a steel disc, but before it is parted off the blade ring is closed on to it by rollers in the manner already described, and the rectangular steel seating ring, which is caulked into a recess in the turbine disc, is also closed on to it in the same way.

The conical ring is then severed from its parent disc. The complete element, consisting of blades, strengthening ring, conical ring and seating ring is then lightly chucked in the lathe and a groove is turned round the outside of each of the strengthening rings.

Into each groove a U-shaped section of extremely thin nickel is inserted and secured by a piece of wire rolled into it. A finishing cut over the nickel fins and on the internal points opposite the corresponding fins of the next smaller blade ring completes the process. The seating ring is fixed into its recess in the turbine disc by means of a piece of iron wire caulked in on one side of it. The ends of this wire are left slightly turned up, so that they can be gripped by a pair of pliers in case it is necessary to extract the ring.

The rings are turned out of solid steel and are designed to expand freely in all directions without distortion. They are mounted on feathers, the fixed ones in the side disc. There are no less than 158 constructions for the steam, although the packing occupies less than 3¼ in. of the shaft. The circumferential labyrinth walls of the rings are turned with thin edges. These edges are then rolled inwards, thus forming minute internal conical flanges. When first made these flanges exactly fit the walls of the next rings, which they embrace, but a few minutes running suffices to wear a minute working clearance, which is maintained unaltered afterwards.

Actual tests showed the leakage steam from both packings of the 1,000 kw. machine amounted to only about 110 lb. per hr. What steam does pass does not find its way into the generator or the engine room, but is led into a chamber, in the side discs, around the packing, whence it is taken to a feed water heater or elsewhere by a special pipe. Not only the shaft-packing but also all other labyrinth packings in the turbine, adjust their own clearances in the same way. On account of the thinness of the fins no dangerous heating occurs in case of contact, even should the running parts shift out of centre. At the same time such an occurrence as this is very carefully guarded against by the self-contained arrangement of the whole plant, its great stiffness and its symmetric form affording temperature differences the least possible chance of altering the central position to which the bearings are originally adjusted. This, together with the very rigid construction of the rotor shaft, which will later be referred to, seems to constitute the necessary conditions for the maintenance of small clearance and leakage in prolonged use and continued safe running of the plant.

The clearances of the labyrinth edges at different radii of the 1,000 kw. turbine from the shaft packing outwards

TURBINE DISC AND BLADE RINGS FOR 1,000 KW TURBINE.

to the larger blade rings, are easily maintained at .004 in. to .010 in., even with the high superheat used. The high pressure being confined to the inner parts, which are of small radius, the leakage as calculated comes out very moderate, even when using steam of very high superheat, as already demonstrated, but also very high pressures.

To start the turbine the handle at the top is screwed back a few turns, and the steam then raises the disc valve from its seat, and equalizes the pressure above and below it. The double heat piston valve above is a sufficiently easy fit in its sleeve to permit of a small amount of leakage past it, and this is quite sufficient to warm up the small mass of the pump in the oil box as the end of the turbine is then worked by hand for a few strokes until the oil pressure is sufficient to raise the piston on the valve spindle against the downward pressure of its spring.

The turbine then starts, and within about ten minutes from the commencement of warming up is running at its full speed of 3,000 revolutions per minute. When starting there is, of course, no reason why the two sides of the turbine should drive their respective alternators at precisely the same speed and, as a matter of fact, they do not do so. But when the speed rises to about 1,400 revolutions the exciting current becomes strong enough to cause the two generators automatically to synchronize themselves and thenceforward to run electrically as one machine. The automatic synchronization can be easily seen by watching the behaviour of the switchboard instruments. The fields of the two machines are connected in series, so that a single field rheostat only is needed, and in ordinary practice no more switches or instruments would be required than are necessary for the control of an ordinary generator.

In case either of the generators become disabled, provision is made for bolting it rigidly to the casing, so that, if necessary, the other generator alone may be used. The result would be a reduction of output by one half, and higher steam consumption per unit, but the frequency and voltage being normal the supply could be maintained in emergency.

There is an arrangement of the emergency trip lever and the valve connected to it which releases the oil pressure and causes the main valve to be closed. The tension cable, already described as causing the stoppage of the turbine if it is slackened by any cause, such as too high speed or unduly heated bearings, passes through the small hole in the toe of the emergency lever. By turning down this lever into a horizontal position the oil pressure is released and the turbine stopped.

This method of stopping can be used whenever desired, as it obviously interferes in no way with the adjustment of the cable. Another point worthy of note is the attachment of the pipe leading from the stop valve to the turbine. This is formed by oxy-acetylene welding, and is designed to prevent expansion troubles from the high superheat, amounting to nearly 300 degrees F., which is normally used. The simple circular form of the valves and casing is maintained with the same object.

For regulation the governor is driven by means of a worm on the generator shaft and has no special features. It controls the stop valve by means of an oil relay. The bearings are short for their diameter and consist of cast iron steps, turned cylindrically on the outside and lined with sheet metal. The two halves are registered by two long pins fitting in holes drilled along the sides of the joint when the halves are clamped together. The set screws holding the half steps together prevent the pins from working out endways. The pair of steps is located centrally by four pads fastened on to the spherical heads of screws which project through the housing, and form a means of adjustment for the position of the shaft.

The bearing caps are secured by taper fitting bolts, with a nut at each end. This type of bolt is used throughout the

turbine, all the casing bolts being thus made. It is claimed that they are very cheaply made and fitted, and when in position they serve to locate the parts they hold together with absolute accuracy. They are easily withdrawn by tightening one of the nuts. The oil supply is led to the bearings by a pipe entering the bottom step. This pipe is placed inside the discharge pipe from the bearing.

The incoming oil passes through holes machined in the bottom step and emerges at the horizontal diameter at one end, whence it flows to the other end along clearances provided for the purpose in the top step. The spent oil returns to the pump from the bottom of the bearing by the outer of the two concentric pipes shown. There is no water cooling of the bearings, the oil alone being relied on to carry away the heat. The circulation of oil amounts to a pint per second for each bearing. The oil pump is of the gear type and is driven directly by the governor spindle.

The oil pump maintains a pressure of about 34 lbs. per sq. in., but this is lowered to about 15 lb. per square in. for the bearings by the use of a reducing valve. The higher pressure is maintained beneath the piston controlling the throttle valve, this pressure being regulated by a slide valve operated by the governor. Variations of oil pressure thus vary the position of the throttle valve, and this. in turn, by means of a floating lever and side shaft, reacts upon the oil system, so as to maintain a onstant relationship between the position of the stop valve and that of the governor.

The force available for keeping the throttle valve closed is about 360 lb., but the spring tension in its working position is double this amount, so that should the emergency device or other cause release the oil pressure a force of about 720 lbs. is applied to the closing of the throttle. A fan maintains an air pressure of 6 in. water gauge in the end of the alternator casing, and thus a tremendous blast is created axially through the machine. The air escapes through orifices in the casing. above the top of the inner generator bearings, and notwithstanding the blast, the machine runs in a way that compares exceedingly well, as to silence, with any ordinary turbo generator.

During the construction of both 500 kw. and the 1,000 kw. machines all work was carried out on a purely manufacturing basis, and exact labor, material and management costs have been kept concerning every important detail. The cost-keeping system was in fact, better than in many manufacturing works, and altogether unusual in connection with work of a preliminary and somewhat experimental nature. From estimates formed on this basis, engineer Ljungstrom says that his turbine is extremely cheap to build.

The inventor says, "that the economy already attained with the Ljungstrom turbo generator for stationary purposes has been sufficiently noteworthy. For marine propulsion, however, the prospects are, I consider, still more favorable with respect to size, cost and efficiency since the voltage need not necessarily be kept constant under various loads. Consequently the stator windings may be calculated for delivering about 70 or 80 per cent. more current than is usual with the same size of the generator, with but a comparatively very small increase in the total losses and with a corresponding increase in effectiveness."

If the electric motors be dimensioned carefully, and for a high peripheral speed, the overall efficiency of the electric transmission turns out to be very high, and exhaustive calculations show that under favorable conditions 90 to 92 per cent. is obtainable. The thermo dynamical efficiency of the turbine, based on results already attained with a 1,000 kw. set, and giving due consideration for later improvements and the larger power, should, for 4,500 kw. at 3,000 revolutions per minute, I consider, reach about 85 per cent.

For a turbo generator and condenser of 4,500 kw. capacity with generators of special design for ship propulsion, the main dimensions are length, 23 ft., 7 in. (7189 mm.) width, 6 ft., 7 in., (2010 mm.) height, including condenser, 14 ft., 6 in., (4420 mm.) The weight of the turbo generator alone is about 34 tons, and the total for the whole plant with pump and water in the condenser, is 65 tons, or 11.5 lb. and 22 lb. per brake horse power respectively. On the exterior the turbo generator is kept at the temperature of the condenser. which has special advantages, particularly in tropical climates.

The weight and size of the electric motors vary considerably with the periodicity, peripheral speed and the proportion of diameter to length. With 50 periods in certain cases, the weight cannot be reduced to less than 38 lbs. (17.25kg.) per brake horse power, whereas in a destroyer, with 100 periods and with the rotors running at 400 to 500 revolutions per minute in a light framing of steel casting or autogeneously welded plating. the weight is about 9 lb. to 10 lb. (4.08 kg. to 4.54 kg.) per brake horse power.

In this case the turbo generators. without condensing machinery, and running at 6,000 revolutions per minute will show about the same weight per brake horse power. With synchronous electric motors on the propeller shafts, manoeuvring does not involve any difficulties, two or three motors may be built together in one casing, and by coupling them in cascade the shaft is caused to run at one half or one third of its normal speed. Other speeds are obtained by slowing down the turbines. On reversing resistances should be switched into the rotor circuits. If these resistances are made adjustable and of ample dimensions, they also may be used exclusively for varying the speed of the motors, thus doing away with the necessity for cascade coupling, or variation in turbine speed.

NEW LABORATORIES OF THE BUREAU OF MINES

Mechanical engineers and others who are interested in the problem of obtaining greater efficiency in the burning of coal, especially since the increase in the price of coal has made the problem even more urgent than ever before, will attend the dedication of the new million-dollar laboratories of the Bureau of Mines, Department of the Interior, in Pittsburgh, Pa., September 29th, 30 and October 1.

The fuel investigations of the Bureau of Mines constitute a large and important part of the work of the Bureau and ample recognition of this fact will be seen in the arrangements of the new laboratories and their equipment for the highest grade of research and routine work. It is here that typical coal, gathered from all parts of the country are analyzed and tabulated in such a manner as to give to the public general information of the coal fields of the country. It is also here that the actual experiments in the combustion of coal take place under experts, and their findings are given publication.

So far has this work advanced that the National Fuel Administration, organized during the war to urge the greatest conservation of fuel as a means of helping to win the war, builded on the work of the bureau of Mines and distributed to the public a large number of the publications of the Bureau, and also called on the bureau in an advisory capacity in many cases.

The Bureau of Mines has been the pioneer in the combustion experiments in the United States, and has already issued a number of reports that are well known to engineers and firemen. It is expected that engineers and men familiar with combustion experiments will attend the dedication showing their interest in Government research in this fundamental field.

The dedication ceremonies promise to bring to Pittsburgh for the three days the most prominent mechanical engineers and mining and metallurgical men of the nation.

A hardening solution for concrete floors that prevents dusting, says "Concrete" is made from sulphate of alumina and acidulated water. To 10 gallons of cold water add 1 fluid ounce of sulphuric acid. Heat the liquid to boiling point and stir in 25 lb. of sulphate of alumina, then let the solution cool and strain. The concrete surface to be treated must first be swept and thoroughly washed. After drying, the hardener is put on in four applications of varying strength, ranging from 30 per cent. solution and 70 per cent. water, up to 100 per cent. solution. The above quantity suffices for the complete treatment of an area of from 50 square yards to 100 square yards. depending upon the porosity of the surface treated.

Power Plant Management—Lubrication

The Following Article Gives Some Interesting Data Relative to Lubrication Problems Encountered in the Power Plant

By ROBERT JUNE, Mechanical Engineer

OF vital importance to the economical operation of the power plant is an accurate knowledge on the part of power plant operators and engineers of lubricants and lubrication. This is true, because even in a plant where the lubricants for each particular service are the ones best adapted to that service, losses of power, caused by friction, may range from 5 to 30 per cent.

With improper lubricants, the losses, due to friction may run much higher, and to these losses may be added the losses due to depreciation of equipment, caused by wear on bearings, guides, cylinders, etc.

As a general proposition, losses due to friction will be found to vary from 8 per cent., in central stations where energy is simply produced, but not utilized, to 25 per cent.; in plants where manufacturing processes are carried on, such as textile, refrigeration, iron and steel, brick and clay, paper, etc. Reducing this power loss friction by 1-10 will generally pay for all lubricants in the course of a year. Hence we are concerned, not with the proposition of saving oil, but with the problem of saving power, for by saving power we may be enabled to save the cost of our lubricants several times over each year.

This is an aspect of the problem of lubrication that is, unfortunately, not generally sufficiently appreciated by the plant manager and superintendent, or by the operating engineer.

The latter know that they get better results with certain lubricants than others, but the value of these results in dollars and cents is almost never placed before them, so that they can vividly realize their importance.

Friction and Lubrication

The function of a lubricant is to reduce friction, which may be defined as the resistance or binding action produced when one body is drawn over another. Friction will vary with the character of the materials, the smoothness of the surfaces, and the pressure exerted to force them together.

Figure I illustrates the conditions existing when bodies of different degrees of smoothness are drawn over each other. It is evident that as the roughness of the surface increases there is a greater tendency for the projections to lock together, and that greater force will be required to draw the bodies with rougher surfaces over each other than to draw those with smoother surfaces.

This clearly illustrates the importance of giving bearings, guides, and cylinders the smoothest possible finish. Unfortunately, we can never obtain complete smoothness of surface with any metal, and must, therefore, content ourselves with obtaining the smoothest surface possible with the particular materials employed.

The purpose of lubrication is to interpose a film of oil between the surfaces, thus forcing them apart so that the actual contact of metal with metal is avoided, and we have only to deal with the fluid friction of the lubricant.

The expression, "fluid friction of the lubricant," may be taken as referring to the resistance of the oil to the force tending to pull its particles apart. This can best be understood by referring to Figure II, wherein an attempt has been made to show the condition of the lubricant in a bearing in action. It will be seen that the oil which is in closest contact with the shaft moves at a much faster rate than that which is in closest contact with the bearing. In other words, we have what may be termed a number

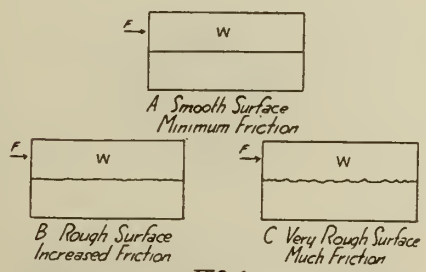


FIG. 1.

of layers of oil between the shaft and the bearing, each moving at a progressively faster rate, depending upon its proximity to the shaft.

It is this condition of fluid friction set up in the oil which makes our choice of a proper lubricant extremely important. The reason for this is that operating conditions vary widely, depending upon the pressure tending to force the bodies together, the temperatures existing at the point at which the lubricant must be used, the speed of one moving body with relation to the other, etc. Obviously, no one lubricant can be expected to meet all conditions of service, so we must find the lubricant best adapted for each particular service.

Characteristics of a Good Lubricant

A good lubricant is that which, for the particular service under consideration, possesses the following characteristics:

1. It should prevent the surfaces from coming into contact under conditions of maximum pressure, and ability to do this is a function of viscosity, or, as it is sometimes called, "body" of the oil.
2. It should absorb and carry away heat.
3. It should have a low co-efficient of friction.
4. It should be of the lowest viscosity consistent with the work required.
5. It should be free from any tendency to oxidize.
6. Temperature of vaporization (flash point) should be high, but its freezing point low.
7. It should be free from acids.

Characteristics of Various Lubricants

Having outlined the qualifications of a good lubricant for any particular service, let us now examine the characteristics of the general lubricants available to see the services for which they are adapted. Lubricants may be divided as follows:

1. Vegetable oils.
2. Animal fats.
3. Mineral oils.
4. Solid lubricants.
5. Greases.

Examining each of these in turn, we find that they possess the following characteristics:

Vegetable Oils.—Vegetable oils consist principally of linseed, castor, rape seed, rosin, cotton seed, etc. These do not, in themselves, possess lubricating properties of any great practical value since they oxidize at comparatively low temperatures and are apt to become thick and gummy after a short use. These oils are therefore of very poor cold test, congealing at a comparatively high temperature, thus making them inconvenient for use in cold weather.

The principal use of these oils for lubricating purposes, is, therefore, confined to compounding with mineral oils for certain purposes.

Animal Fats. — Animal oils in general use, are tallow, neat's-foot oil, lard, sperm oil, wool grease, fish oils, etc. Individually, these oils possess the same objectionable features as vegetable oils. They are, therefore, seldom used in a pure state, but are, on the contrary, frequently compounded with mineral oils. The reason for this compounding, when done, is that the animal oils in general have better lubricating qualities than pure mineral oils of equal viscosity or body.

In cylinder lubrication, especially in the presence of moisture caused by steam, the addition of 2 to 5 per cent. of tallow seems to increase the lubricating effects. When used in these proportions the bad effects from the decomposition of the tallow, which may set free acids which attack the metal, and the bad effects of gumming or oxida-

tion, are not so great as to overbalance the advantage of lubrication.

Mineral Oils.—Mineral oils have many advantages as lubricants over animal or vegetable oils:

1. In their cheapness.

2. Being of non-organic origin they are of more stable chemical composition and do not tend so readily to change their condition by becoming rancid, thick or gummy, by exposure to the air, and they have no corrosive action on metals.

3. By what is known as fractional distillation, mineral oils can be separated into a great many different grades, from the lightest spindle oils to the dense, heavy cylinder oils.

4. They are of lower coal test and not so liable to spontaneous combustion as the animal fats.

5. They present wider range of lubricating properties than those derived from animal or vegetable sources—the thinnest being more fluid than sperm; and the thickest more viscous than fats and tallows.

Mineral oils may be classified as:

1. Distilled oils, which are produced by distillation from crude petroleum, and are so treated by various processes in which alkalis and acids are employed as to appear in the finished product as transparent fluids of extremely stable composition.

2. Natural oils, which are prepared crude petroleum, from which grit is suspended and tarry impurities have been removed. They are usually dark, opaque, and rich in lubricating properties.

3. Reduced oils or, as they are sometimes termed, heavy, natural oils, from which the lighter hydro-carbons have been evaporated, and from which the tarry residue has been removed by filtration.

Solid Lubricants.—Mica, soap-stone and dry graphite, are the principal solid lubricants. When used, they are mixed with grease or oils. Their principal use is to be found at points where great weights have to be carried on small areas, and is usually confined to low speeds. The co-efficient of friction of solid lubricants is high, and they are, therefore, not particularly economical. Better results can usually be secured by the use of larger bearing surfaces, but when design does not permit of this, there is a real field open for their use. Under certain conditions of speed, solid lubricants will sustain pressures under which no liquid would work.

Graphite exists in two forms—flake and amorphous. Crystalline graphite or flake graphite is dense and compact and is not easily reduced by crushing between the fingers, so that the individual particles maintain their size. "Amorphous" graphite, under pressure, continues to be reduced in size until the particles are no longer evident to the touch. Flake graphite is the better lubricant, because it has good wearing qualities and adheres to metallic surfaces with which it comes into contact. Graphite is not affected by heat. The value of flake graphite as a lubricant lies in its property of filling any irregularities that exist in a bearing surface, thus reducing the roughness of the surface and producing a better surface for lubrication with oil or grease.

Graphite is of value as a lubricant for steam engine cylinders, provided it is used in great moderation and not fed in excess. The entire value of graphite as a lubricant is lost if an excessive amount is used.

When the valve seats and cylinder walls of an engine are badly cut or scored, the addition of a little graphite, (several teaspoonfuls), mixed with the cylinder oil, will greatly aid in smoothing up the bearing surfaces.

For steam engine cylinders using superheated steam, flake graphite is of great value. It aids in filling up the irregularities of the cylinder wall surfaces, so that the cylinder oil, which is greatly reduced in viscosity by the high temperatures found in these cylinders, will have the best possible surface conditions to work on.

In order to obtain a clear idea of the value of graphite as a lubricant, the engineer must appreciate the fact that in order to be efficient, graphite must

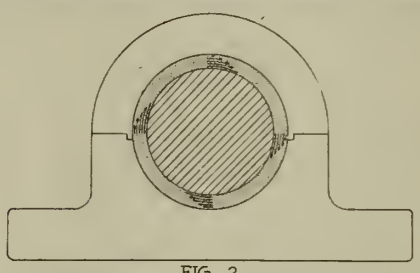

FIG 2

Illustrating the relative speeds of the various layers of oil surrounding shaft in bearing

identify itself with the metallic surfaces to be lubricated. Its function is to fill up the pores and depressions in the surfaces, giving them a smooth polished finish. Lubricating oil must then be introduced between the rubbing surfaces so as to produce a film, which will be more efficient in its results because of the reduced frictional resistance to be overcome, due to the graphited surfaces.

The specific gravity of graphite is 1.81, and, therefore, is greater than that of oil, and for this reason it will settle out of oil on standing. It is not possible to permanently suspend graphite in oil. A mixture of oil and graphite should never be put in an oil cup or sight-feed lubricator, as the graphite will soon clog the feed passages.

For engine bearings a heaping teaspoonful of graphite to a pint of oil is sufficient.

About 4 per cent. by weight of graphite is the average good practice when mixed with oils and greases, and gives good results when applied at reasonably long intervals.

Graphite should never be used on bearings supplied with forced or flooded continuous lubrication.

Lubricating Greases.—Petroleum cup greases consist of lime soaps, mineral greases, and rosin oils. Soap gives the grease melting-point and body. Nevertheless, greases are excellent lubricants when properly used, but they have, however, a very narrow range of service and they should not be called upon to perform the function of lubrication under conditions to which they are not suited.

The use of any solidified lubricant places a drag or friction load on the machine it is used upon. The chief advantage of grease as a lubricant lies in its cleanliness and in its property to "stay put." In bearings revolving at a slow speed, where it would be difficult to maintain a film of lubricant, grease may be used to advantage.

For crank-pin bearings of high-speed engines, grease will give satisfactory results. In the case of the low speed bearings mentioned above, grease is an efficient lubricant, because, due to its adhesiveness, it will maintain a layer of lubricant when the machine is at rest, and thus reduce the starting friction when the machine is placed in operation.

Testing Lubricants

While it is possible to lay out quite elaborate specifications for lubricants, covering every type of service, the fact, nevertheless, remains that these specifications are, after all, only a starting point.

After the particular lubricant has been chosen, by specification, it remains to test it out under actual working conditions, and then to try other lubricants whose general nature is such as to lead the engineer to believe that success might attend their use. Only by comparing the performance of a number of lubricants under actual working conditions can the best lubricant for the particular service under consideration be chosen. Our first step, however, is to choose our several lubricants which we expect to test out intelligently. In order to do this it may be well to review the tests and specifications used by large consumers in the purchase of lubricants.

The test of an oil consists of three parts—chemical, physical, and practical.

Chemical Tests of Lubricating Oils.—To pass the chemical tests of the Navy Department, "all oils should be neutral in reaction and should not show the presence of moisture, matter insoluble in petroleum ether (hard asphalt), matter insoluble in ether alcohol (soft asphalt), free sulphur, charring or wax-like constituents, naphthenic acids, sulphonated oils, soap resin, or tarry constituents, the presence of which indicates adulteration or lack of proper refining. Except in oil for engines without forced lubrication, no traces of fixed oils (animal or vegetable fats) should be found.

"In lubricating oil for main engines without forced lubrication, approved

fixe doils, such as rapeseed, olive, tallow, lard and neat's-foot oil, may be used, when the foregoing fixed oils are used, they must be well refined with alkalies, unadulterated, containing a minimum of free fatty acids, with no moisture or gumming constituents. Olive oil should not have a high specific gravity. If satisfactory emulsifying results can be obtained with straight mineral oils on engines without forced lubrication, they may be submitted for service test."

While the small plant owner is not usually in a position to have various tests for oil made in his plant, he can usually have them made by a commercial laboratory at a cost, which, in view of the possible savings to be effected, is well worth the time and expense involved. Large plants, of course, often possess laboratories and are in a position to make the tests themselves.

The procedure may be outlined as follows:

Moisture Test.—Wet the walls of a test tube with the oil under investigation, then put three or four cc of the oil in a tube and place in a bath of liquid paraffin which should be brought up to a degree of 300 degrees Fahr. If the oil contains water, emulsions will form on the walls, and foaming and sputtering will be noted.

Sulphur Test.—Take a small piece of metallic sodium, the size of the little finger nail, boil it in 50 cc of the oil in a test tube for 30 minutes. At the end of this time, add an equal amount of water and again place over the burner flame until the sodium is dissolved. After the sodium has disappeared pour off the water and pour in one per cent. solution of sodium nitroprusside. If the mixture turns violet color, the oil contains sulphur.

Tests for Acid Alkalies.—Pour 25 cc of oil and twice as much of distilled water into the test tube; boil for several minutes, dividing the mixture into two portions; add methylporange to determine acids, to one portion, and to the other add phenolphthalein for the determination of alkalies. The formation of emulsions in either test tube will indicate the presence of acid or alkali as the case may be. Acids cause corrosion and should be religiously avoided.

Tests for Matter Insoluble in Ether.—Place 14 cc of ether alcohol (which consists of 8 parts of ether and 6 parts of alcohol) and 11 cc of oil in the test tube—shake thoroughly for a minute or two—then allow the two to stand for twelve hours. At the end of this time if there is any precipitation at the bottom of the tube, it will be asphalt. Even a trace of asphalt makes the lubricant undesirable, since it causes scoring of journals and clogging of oil lines.

Tests for Matter Insoluble in High Grade Gasoline.—Filter several times 300 cc of 86 to 88 Baume gasoline. Place in an absolutely clean or dustpro f glass receptacle. Sprinkle 2 cc of oil into the gasoline and allow to stand for 12 hours. If there is any precipitate at the end of that time it will consist of soft asphalt or carbon particles, and even a slight trace would make the oil extremely undesirable.

Test for Tarry or Suspended Matter.—This test is carried out in the same manner as the previous one, using, however, 95 cc of gasoline and 5 cc of oil. The receptacle may be examined for precipitate at the end of half an hour.

Test to Determine Mineral or Vegetable Oils.—Take a small piece of metallic sodium and bring to a boil in 10 cc of oil. The presence of animal or vegetable oils will be indicated if the mixture becomes gelatinized or semi-solid.

Test for Presence of Undesirable Carbon or Hydro Carbon.—This test is made by simply heating a small quantity of oil in test tube to a boil, and then comparing the color of the heated oil with that of unheated. If there is any discoloration in the oil it indicates the presence of undesirable constituents.

Gumming Test.—This test indicates the extent to which the oil has been refined and will, therefore, serve as a guide to indicate the extent to which oil may be expected to oxidize or gum when in use. This test is undoubtedly of great value and it should always be made when opportunity is afforded. It consists simply of mixing a small quantity of oil in the test tube with an equal quantity of nitro sulphuric acid, and it the oil has been properly refined, no change will be noted, but if the oil has been poorly refined, the fact will become evident by the simple separation of material of dark color. This separation is the result of oxidation of tarry matter in the lubricant.

It has been found that the result obtained by the gumming tests compare almost exactly in results with what is known as the carbon residue test, which is made by distilling the oil to dryness in the test tube. This carbon residue test has been found of great assistance in choosing a satisfactory cylinder lubricant for gas engines, as the presence of carbon always and invariably means trouble in gas engine cylinders.

Tests which have just been outlined are easily within range of even the small plant operator and the writer believes that the investigation of the characteristics of the oils being used is well worth the attention of operators in both large and small plants.

This is particularly true because of the fact that the presence of undesirable matter in the oils may mean very heavy costs for repairs to equipment, and may even cause a shut-down of the plant at critical moments.

Next month we will take up physical tests of lubricating oils and will then discuss the characteristics of oils for various services.

KEEP BUSY, KID!

Beware the deadly sitting habit,
Or if you sit be like the rabbit,
Who's ever ready for the jump,
By springs concealed beneath his rump.

A little ginger 'neath the tail,
Will oft for lack of brain avail.
Eschew the warm but slothful seat,
And move about with nimble feet.

And so, my son, avoid the snare
That lurks within the easy chair.
To meet each duty quick and well
Both feet must hit the pike like ——!

The National Engineer.

THEY SPEAK OF CABBAGES AND KINGS

Topics of Discussion Are New And Change as Quickly as the Seasons

A Canadian who calls on the machinery trade in United States, submits the following:—

Some well-informed person should compile a book which would enable Canadians intending to visit the United States, to discuss with satisfactory assurance many of the ponderous questions which our being hurled at them somewhat persistently. Here are some of them.

What does Canada do with all her import duties?

What are you going to do about these exchange rates?

What do you think about Pershing?

When is Canada going wet again?

What's the labor situation, if any?

Who is the Prince going to marry?

What do you think of Woodrow, anyhow?

What about your returned soldiers?

If we didn't win it, who did?

* * *

No longer is first place given to such burning topics as: "Why do people marry Lillian Russell?" or "Who makes Queen Mary's millinery?" Canadians who get past the U. S. immigration officials find that the great American people are taking a keener interest in Canadian affairs—that is affairs that may be said to have an international bearing.

* * *

Space is Cramped.—American machinery manufacturers who visited the National Exposition at Toronto, express themselves as surprised that, considering the splendid showing by other industries, the machinery industry should be confined to such limited quarters as the present machinery hall. The display is regarded as by no means representative of Canadian enterprise. A Galt manufacturer suggests that a new building should be of sufficient size to permit of displays being grouped according to towns or cities. Galt alone, he declares, could just about fill the present structure if all firms were represented.

Air Lift Installation with Special Features

A Highly Efficient Air Lift Installation at Fort Bliss, Texas, Which Incorporates Some Novel Features of Design. Reprinted From "Compressed Air"

By CAPTAIN J. F. BROWN

CAREFUL analyses of conditions to be met and thorough study of air lifts in successful operation have made possible the design and installation of such a plant at Fort Bliss, Texas, tests of which show operating efficiencies never before attained—51.9 per cent. as the average of the better of two sets of air lift tests, and 28.66 per cent. as the corresponding over all or wire-to-water efficiency.

The footpiece, Fig. 2, consisting of a double conical bronze casting (inverted at lower end), set within and at the foot of the eduction pipe, is the special feature of design. Particular attention was also given to the proportions of the eduction pipe and to the head tanks at the top of each eduction column. Small water storage reservoirs, with sand settling compartments and measuring wires, are provided.

Water for all needs of the permanent military establishment, as well as for several bodies of troops encamped temporarily on the Fort Bliss military reservation, is supplied from four bored wells, each 600 ft. deep, and is pumped from these wells into surface reservoirs by means of compressed air. From the surface reservoirs the water is pumped directly into the distributing mains by centrifugal pumps.

These wells, two of which are 10 in. and the other two 12 in. in diameter, are cased to the full depth with standard threaded steel casing. From the normal water plane to the bottom the casings are perforated with ½ x 10 in. vertical slots, the area of opening being 10 sq. in. per foot of casing. In the 10 in. wells drilled in 1913 the slots were cut by means of air operated hammers, while in the larger wells, drilled in 1917, they were cut by an oxy-acetylene torch. The latter method proved to be much more rapid and less costly than the former.

Following are the piping details of the several wells:

Well No. 1

Diameter 10 in.
Total depth 615 ft.

Water Discharge Piping

4 in. dia. 20 ft. below foot piece.
1 ft. 4 in. length of foot piece.

Piping Above Foot Piece

4 in. dia. 100 ft. 3 in.
4½ in. dia. 160 ft. 0 in.
5 in. dia. 253 ft. 5 in.
6 ft. dia. 23 ft. 3 in.

536 ft. total distance from foot piece to separator tank above the ground.

Well No. 2

Diameter 10 in.
Total depth 615 ft.

Water Discharge Piping

4 in. dia. 20 ft. 3 in. below foot piece
1 ft. 4 in. length of foot piece.

Piping Above Foot Piece

4 in. dia. 106 ft. 1 in.
4½ in. dia. 160 ft. 4 in.
5 in. dia. 274 ft. 7 in.
6 in. dia. 11 ft. 0 in.

553 ft. 4 in. total distance from foot piece to separator tank above the ground.

Well No. 3

Diameter 12 in.
Total depth 615 ft.

Water Discharge Piping

4 in. dia. 21 ft. below foot piece.
1 ft. 4 in. length of foot piece.

222 ft. depth to water level when not pumping.

234 ft. depth to water level when pumping.

135 lb. gage, air pressure, starting.

130 lb. gage, air pressure, running.

Air for operating the four wells is supplied by four Ingersoll-Rand duplex two-stage compressors, two of which are equipped with high and low-pressure cylinders 7½ in. and 14 in. dia., respectively, the other two having cylinders 7 in. and 12 in., and all having a 12 in. stroke. At the normal speed of 190 r.p.m. the two larger compressors deliver 320 cu. ft. per min. each, and the smaller 260 cu. ft. each, operating against a terminal pressure of about 150 lb.

All of the compressors discharge into a 6 in. header, at each end of which is an air receiver 3½ ft. dia. and 10 ft. long. From each receiver compressed air is distributed to two wells, the air supply line to each well being 3 in. At the well head the air line is reduced to 2 in. and extends into the well between the casing and the eduction column to a depth of approximately 540 ft., at each point it connects into a specially designed bronze foot piece.

The function of the foot piece, Fig. 2, is to facilitate the thorough mixing of the current of air and the rising column of water. This highly important feature of the installation differs radically from the well-known commercial types of foot pieces. It consists essentially of a double conical bronze casting supported concentrically within the eduction column, the apex of the lower cone extending just into the compressed air inlet. From this point the velocity of the rising column of water is increased, due to the decreased area of the section, until the throat section of the base of the cone is reached, at which point the velocities of the two currents are very nearly equal. In this portion of the foot piece there occurs the thorough mixing of air and water, the two fluids passing through the throat section in a thin sheet or film. The upper cone serves to provide a steadily increasing section, thus preventing a separation of air and water, which would be caused by the shock due to a suddenly increasing section. The eduction column was designed of such proportions that the maximum velocity of the rising column of water and air should not exceed 25 ft. per second at any point when the well was delivering at the normal rate, and increases in diameter from 4 in. at the foot piece to 7 in. at the top.

At the upper end of each eduction column is a cylindrical steel head tank, Fig. 3, 3½ ft. in diameter and 3½ ft. in depth, within which is supported, just above the end of the pipe, an umbrella-shaped cast-iron deflecting vane, whose function is to break the force of the rising column of water and air. The head tanks are closed at their tops by means of steel plates, bolted on over rubber gaskets to prevent the escape of air. From the head tanks water and air flow through 8-in. galvanized-steel pipe lines supported on angle-iron frames and concrete piers, to two covered rectangular reinforced-concrete reservoirs of 46,000 gal. capacity each. Each

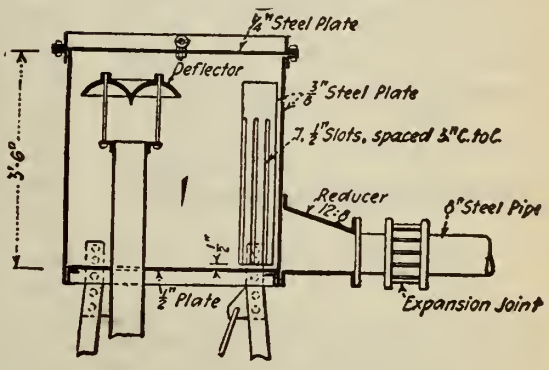

FIG. 3—AIR LIFT TANK.

reservoir contains a small settling chamber, in which the sand coming from the wells subsides, and a rectangular weir for measuring the rate of discharge from the wells. Fig. 4.

Horizontal, double-suction, single-stage, volute-type, centrifugal pumps are used for pumping the water from the surface reservoirs into the distributing mains. There are four of these pumps, each rated to discharge 600 gal. per minute against a head of 135 ft. at a speed of 1,760 r.p.m., although two of them have a discharging rate of about 1,000 gal. per minute when operating against that head.

All of the compressors and centrifugal pumps are driven by constant-speed, induction-type motors. The motors for the two larger compressors are rated at 75 h.p. each and operate at a speed of 580 r.p.m., while those for the two smaller compressors are rated at 61 h.p. each and operate at a constant speed of 1,150 r.p.m. Each centrifugal pump

SUMMARY OF AIR LIFT TESTS AT FORT BLISS

is direct-connected by means of a flexible coupling to a 40 h.p. motor, which operates at a constant speed of 1,760 r.p.m.

Upon completion of the original installation, consisting of the two larger compressors and two centrifugal pumps, a series of tests, or trial runs, was made to ascertain the efficiency of operation of the plant, particularly of that portion of the plant used for lifting water from the wells. During the past year the capacity of the plant has been practically doubled by the installation of additional compressors and pumps, and upon completion of this work a second and more comprehensive series of tests was made.

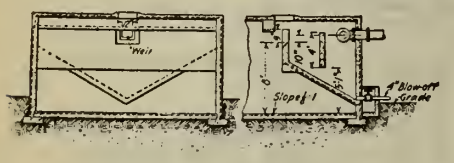

FIG. 4—RESERVOIR WITH SAND SETTLING COMPARTMENT AND WEIR.

In preparing the plans and specifications for the plant consideration was given to the desirability of making frequent operating tests of the different portions of the plant, with the result that it was determined to provide in the permanent installation such gages and meters as would be necessary in obtaining the desired data.

The series of tests, or trial runs, on the air-lift installations is divided into two sets. In the first set, the power input to the compressor motors was obtained from readings of the recording dials of the watt-hour meters on the switchboard; the speeds of the motors and compressors by means of revolution and stroke counters; the rate of delivery of compressed air to the wells from readings of the scale of the manometer of the air meter; the air pressure from gages on the air receivers and at each well head; and the rate of delivery of water from the wells from the weir gage. In the second set of tests the power input to the compressor motors was obtained by counting the number of revolutions of the rotating disks in the recording watt-hour meters, the rate of delivery of water from the wells from actual volumetric measurements by means of the surface reservoirs, and all other data as in the first set. The methods of obtaining the power input to the motors and the rate of delivery from the wells, as used in the second tests, are thought to be much more accurate than those used in previous tests, because unit rates are derived from totals for a given period of time rather than from direct observations.

Results calculated from data obtained during the tests described are given in the accompanying table. The average efficiency of the air-lift for the first set of tests was 48.1 per cent. and for the second tests, 51.9 per cent. The average overall efficiency (wire to water) for the airlift end of the plant for the first set of tests was 26.4 per cent. for the first and 28.66 per cent. for the second set of tests.

The average power requirement for lifting water from the wells to the surface reservoirs is 2.77 kw.-hr. per 1,000 gal. of water, and that for pumping the water from the surface reservoirs into the distributing system is 0.798 kw.-hr. per 1,000 gal., under average working conditions of pressure and rate of delivery. At an average cost of 1.5c per kilowatt-hour, the actual cost for power alone for delivering 1,000 gal. of water into the distributing system is 5.31c. The cost for the pumping station crew, consisting of a chief engineer and one assistant engineer and one laborer on each of three daily shifts, and also including the cost of incidental supplies, such as lubricating oil and waste, is 1.66c per 1,000 gal., making the total actual cost 7c per 1,000 gal. The actual outlay of funds for this plant is $101,767, the original installation, including the two 10-in. wells, having cost $42,700 and the addition to the plant, including the two 12-in. wells, having cost $64,067. Interest at the rate of 4 per cent. upon the cost of the installation, and depreciation of equipment at the rate of 5 per cent., are provided for by adding 2.63c per 1,000 gal., making the total cost for supplying water 9.63c per 1,000 gal., on the basis of a plant capacity of 1,000,000 gal per day. Prior to the completion of the plant, water purchased from the El Paso Water Co. to supply the needs of Fort Bliss cost 20c per 1,000 gal. At an average daily demand of 1,000,000 gal., the annual saving to the Government effected by the operation of this plant is $37,850. If the plant capacity is taken as 1,500,000 gal. per day, which is its normal working capacity, providing for the shutting down of one compressor and one well, the total cost of supplying water is 8.21c per 1,000 gal., and the annual saving to the Government is $64.550. Taking the plant capacity as 2,000,000 gal. per day, which is the ultimate capacity of the present installation, the total cost per 1,000 gal. is 6.74c, and the annual saving is $96,798.

SCIENCE BEHIND LABOR

Sir Richard Gregory, who is mainly responsible for organizing the British Scientific Products Exhibition in London, makes this claim on behalf of the national value of the man of science: "It is not generally understood how the work at British universities and other institutions for higher training is bound up with national welfare. When necessity demanded, our men of science showed that in every direction they could devise means of offence and defence superior to those of the foe against whom our armies had to contend. The way in which, during the war, the universities faced problems of an entirely novel character, and concentrated attention upon them until solutions were reached, is an earnest of what they can accomplish for industry in times of peace, and it is to be hoped that this factor of progress will continue to play an important part in national life. Great industrial developments depend upon new knowledge obtained by scientific investigation, and the exploitation of that knowledge in invention and industry. It is the business of the scientific investigator to discover new facts or principles, and of the engineer or inventor to recognize and apply the results achieved. Labor alone may build Pyramids, as it did four thousand years ago, but it cannot create new industries without new knowledge, and this is obtained by scientific research, whether secured in the laboratories of universities or of works."

BRITISH SCIENCE AND ENGINEERING

Professor J. C. McLennan, scientific adviser to the British Admiralty, recently read a paper before the North-East Coast Institution of Engineers and Shipbuilders on the application of science to marine problems. Incidentally the paper reveals the high standard which British scientific engineering reached in dealing with the special difficulties which had to be met durng the past few years. Conspicuous among the devices developed originally for anti-submarine purposes but certain to be invaluable to shipping under peace conditions is the hydrophone—an instrument which detects underwater vibrations set up by a moving vessel. Microphones and magnetophones of exceedingly high sensitiveness were employed, sometimes with attachments which enabled the listener to ascertain the direction from which the disturbance was coming. The "silent submarine" was, however, introduced to circumvent the hydrophone, and this development was countered by the "echo method" under which a beam of sound was sent out by the chasing vessel, sweeping the seas like a searchlight, and causing an echo when it strikes a solid object such as a submarine. Even more ingenious is the "leader gear," invented by the British for another purpose. If a cable laid on the bottom of the sea—say in the channel leading into a harbor—is traversed by alternating current, it is possible, by means of delicate devices installed on board ship, for the navigator to see or hear indications of the presence of such a cable. So perfect is the mechanism that a ship can proceed at 20 knots in fogs or darkness, feeling its way along the cable almost as precisely as a tramcar trolley follows the overhead wire. Professor McLennan states that "by leader gear law in such areas as the River St. Lawrence, the entrance to the Thames or Halifax Harbor, the Straits of Dover, etc., in and out lanes of traffic can be maintained with ease in fogs." The echo method can also be used for sounding, for locating icebergs, surface vessels, and rock-bound coasts in a fog. In fact, "under peace conditions many important technical systems and devices brought forward during the war will find immediate application as aids to navigation."

The Contraflo System of Utilizing Exhaust

By Means of This Arrangement All the Heat of Exhaust Steam From Engine Room Auxiliaries is Made Available and Less of the Heat in Main Engine Exhaust is Rejected

THIS system of condensing, vacuum producing, filtering, and feed heating apparatus which was primarily developed by Mr. D. B. Morrison, of Messrs. Richardson, Westgarth & Co., Hartlepool, England, a number of years ago, and has since been extended and further improved by the Contraflo Condenser and Kinetic Air Pump Syndicate, London, England, is now being manufactured in Canada under license by the Goldie & McCulloch Co., Limited, Galt, Ont.

The objects of the Contraflo system are:—

To return to the boiler by means of the feed water the entire heat in the exhaust steam from the auxiliary engines, thereby economizing coal.

To realize this thermal gain in all seas by means of a "Contraflo" condenser, which continuously maintains the highest economical vacuum with the least pumping power.

To increase the propelling power of the main engines without increasing the coal bill.

It has been established that with the "Contraflo" system of vacuum producing a higher vacuum can be obtained with smaller cooling surface than with the ordinary surface condenser, thus leading to greater power being developed in the main engine. Also by means of the steam ejector (which is part of the "Contraflo" system and is described hereafter), this higher vacuum is produced not only without cooling down the condensate (boiler feed water), as would be the case with an ordinary condenser when endeavoring to obtain higher vacuum, but the condensate is delivered to the air pump at a higher temperature than usual, thus leading to economy in the boiler room.

As regards the "Contraflo" system of auxiliary condensing and feed water heating and filtering apparatus, one of the principal features of this is the small size of the winch condenser required. The "Contraflo" winch condenser is usually fitted in connection with the "Contraflo" compensator heater and the "Contraflo" cascade feed water filtering, cleansing, and heating tank. The exhaust from the various auxiliaries is all utilized, partly in being condensed into boiler feed water and partly for the purpose of heating up the boiler feed water, but eventually ALL exhaust steam becomes boiler feed water and the system is so flexible that the temperature of feed can be regulated to almost any desired extent on either the suction or the delivery of the delivery side of the boiler feed pumps.

The "Contraflo" cascade filtering and heating tank receives the water discharged by the engine air pump, the drains from the I.P. and L.P. receivers, and all other drains from around the engine room and from the winch condenser and compensator heater; it also receives such exhaust steam as is not used in the compensator heater for heating feed water on its way to the boilers or which is not condensed in the winch condenser and returned from thence to the cascade tank as hot water. This steam can therefore be utilized for heating feed water on the "Cascade" tank on the suction side of the pumps. The tank is arranged with special heating nozzles and a system of filtering and baffling to separate oil and foul water from the cleansed and heated feed water.

The feed pumps, either engine driven or independently driven, receive this cleansed water and deliver it through the "Contraflo" compensator heater, where it is further heated by a portion of the exhaust from auxiliaries, as mentioned above. The portion of the exhaust steam not used in the heater will, as occasion arises, either pass partly to the winch condenser and thence back to the Cascade tank as hot water, or else go direct to the Cascade tank as already described; all these operations are practically automatically controlled once the regulating valves on the pipe lines are properly adjusted.

The "Contraflo" winch condenser is arranged with temperature control so that should the feed water coming from it to the Cascade tank and thence on to the suction side of the feed pumps, be too hot for the pumps to deal with, it can be regulated to a temperature the pumps can handle and the greater portion of the feed heating then is done in the Contraflo compensator heater, placed on the discharge side of the pumps.

By utilizing portion of the exhaust steam to heat the feed water in the Cascade filter tank the compensator feed heater can be made much smaller than is usual in ordinary practice where the whole of the exhaust steam is passed through the heater; also an effective device is fitted for collecting and removing air both from the steam chamber and the water heads, this generally being overlooked in ordinary practice.

HEAT TO
ENGINE
HEAT IN EXHAUST STEAM
HEAT CONVERTED INTO WORK

THE DISTRIBUTION OF HEAT IN EXHAUST SYSTEM

It will be seen from the foregoing that ALL the heat in the exhaust from the engine room and deck auxiliary machinery and all drain water from main engine and auxiliaries is utilized in heating the feed water, also that ALL the exhaust eventually becomes feed water.

Another feature of the "Contraflo"

auxiliary system is the very complete method adopted of removing oil and grease from the exhaust steam and feed water, a special oil and grease separator being placed close to the compensator heater, and the winch condenser also having an oil extracting device; likewise the Cascade tank has an effective oil collecting and filtering medium and a system of baffling, all of which make for feed water very free from oil.

Regarding the main condensing system, the principal feature of this consists in combining a small auxiliary jet condenser or receiver tank in series with the main condenser and fitting an ejector or inducing nozzle on the main condenser to withdraw the comparatively richly air-laden vapor, which usually remains in a condenser despite the efforts of the air pump to withdraw it.

In an ordinary condenser the lower rows of tubes soon lose their efficiency due to oil being deposited on their surfaces and also on account of water dripping on to them from the upper tubes and preventing the steam from getting into close contact with the cooling surface. Every sea-going engineer knows that to maintain a vacuum of more than 23¼" or 24" in warm water entails the pumping of a large amount of circulating water, but in the Contraflo system, on account of the large volume of steam and air removed by the inducing nozzle it has been demonstrated that a vacuum of 27" can be maintained in the main condenser, with sea water at 80° to 85° F.; also that the cooling surface can be materially reduced.

The ejector receives its steam supply usually from the circulating pump engine exhaust and delivers the steam and air mixture to the small jet condenser, which is placed on the air pump suction pipe. The condensing water used in this jet condenser is simply a small amount of the condensate discharged by the air pump and is drawn back to the jet condenser and thence again passes back into the air pump, being in effect a closed system. A water seat or U leg is formed between main condenser and air pump on the air pump suction pipe, to prevent the air and water vapor discharged by the ejector returning back to the main condenser.

On account of the smaller condensing surface required in the "Contraflo" system due to the employment of the steam jet, etc., a lesser quantity of circulating water is required and therefore a smaller circulating pump; also less of the heat in the exhaust steam from the low pressure cylinder of the main engine is transferred to the circulating water and lost overboard, as the steam ejector replaces about one-fifth of the tube surface normally required and collects a large

FEED PUMP SUCTION VALVE
LEVELS

volume of uncondensed steam and vapor from the main condenser and delivers it into the small jet condenser, where its heat is transferred to the condensate (or boiler feed water), as is also the heat in the steam passing through the ejector from the circulating pump engine exhaust.

The recognized best cargo steamer practice as recommended by the guidance specification of the North-east Coast Institution of Engineers and Shipbuilders provides for 1½ sq. ft. of condensing surface per normal indicated horse-power at sea; on this basis 2,000 h.p. would require 3,000 sq. ft., or, say, 15,300 lineal feet of brass tubing ¾ in. diameter. By installing the "Contraflo" system for main condenser about one-fifth of this tubing could be saved.

A test was carried out in England some time ago in the presence of representatives of the British Controller of Shipping, the North-east Institution of Engineers and Shipbuilders and other bodies, to determine the relative efficiency of the "Contraflo" winch condenser, as compared with one of ordinary circular shell type. The result showed that a "Contraflo" condenser of 250 sq. ft. could effectively perform the same duty as ordinary condenser of 600 sq. ft. surface, the duty in this case being to condense 15,000 lbs. steam per hour. The weight of the "Contraflo" condenser was 30% less; the saving in cost on 100 winch condensers supplied for British standard ships was $89,000. The "Contraflo" system has been largely adopted in the British mercantile marine and that of other countries and a contract has recently been entered into with the United States Emergency Fleet Corporation for the supply of this apparatus on 320 ships with the option of putting it on all they build. The system is also being fitted on a number of vessels building in Canada.

The cuts accompanying this article illustrate some of the "Contraflo" details.

Cut No. 1 illustrates diagrammatically the quantity of heat in steam taken from a ship's boilers for the auxiliary machinery, and also how much of this heat is returned to the boiler with the feed water under the "Contraflo" system.

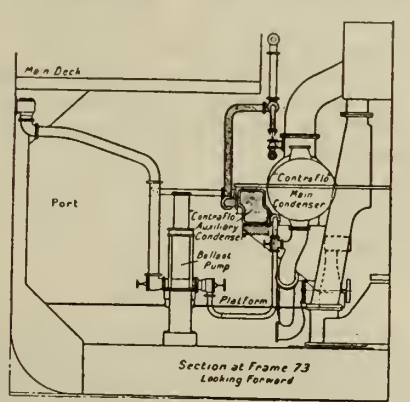
Cut. No. 2 illustrates the latest and simplest arrangement of the "Contraflo" auxiliary system and piping connections in diagrammatic form; this is the system that is now being fitted to the British standard ships. The letter press with this cut gives the setting and operation of the various valves.

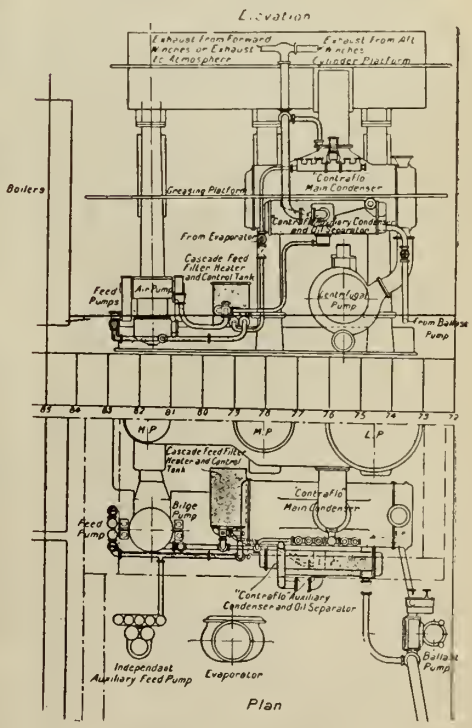
Cut. No. 3 shows the cascade filter tank in its proper relative position as regards levels in connection with feed pump valves of the main engine. For independent feed pumps the water level over the suction valves of the pumps should be the same as for engine-driven pumps.

Cuts Nos. 4 and 5 show a new arrangement of the main engine and auxiliary machinery covered by the "Contraflo" patents and being fitted to British standard ships. These are specially interesting as showing the centrifugal pump, cascade tank, and winch condenser all directly attached to the main engine, thus permitting the piping in connection with same being fitted and assembled in the shops, whereas with the ordinary arrangement most of this piping would otherwise have to be fitted aboard ship. The new arrangement results in both a saving of piping and of labor, because in the ordinary ship board arrangements of auxiliaries and piping only about 27% of the total piping in the system can be fitted in the shops, yet under the new "Contraflo" arrangement as illustrated it is possible to fit up to 60% of the piping in the shops and the piping is considerably shorter. Cut No. 5 also shows the auxiliary jet condenser fitted on the air pump suction pipe in conjunction with the steam ejector system.

There are various other arrangements of the "Contraflo" system to suit special requirements, one of these modifications being the elimination of the engine-driven air pump and its replacement by a small rotary kinetic air pump and condensate pump combined in one casing and driven by a small steam turbine; this is used in conjunction with the steam ejector system and is specially suitable for large powered vessels, resulting in a very appreciable saving in cost, weight and space.

The Navy Department has adopted an audio frequency signal for aviators which will enable them to land with safety in a dense fog or in the dark. This system of audio transmission which has been perfected has played a conspicuous part in the war and is now being applied to the uses of peace. It will be of advantage to navigators finding their way through fog into port, as well as to navigators in the air The difficulties encountered because of fog in the recent transatlantic flights of the NC-4's and the Vickers-Vimy airplane demonstrate the need of just such a device.





Refrigerating Plant Efficiency

Rules and Information on Correct Proportions as One of the Essentials for Maximum Operating Plant Economy

Reprinted from the "Refrigerating World."

By GEORGE NAYLOR

CORRECT proportions is one of the essentials for maximum operating economy in the refrigerating plant. Every machine, device, apparatus or piece of equipment will give its most efficient service at a certain load; above this, or below, the cost or effort of operation increases. Consequently it must be the aim of the man in charge of the plant to maintain this proportion as far as possible and run the plant at its maximum efficient point as near as possible.

Of course, the designer of the plant is largely responsible for the proportioning of the equipment when the plant is erected and there is nothing left for the operating man to do but to make the best of what is already installed, as far as this is concerned; on the other hand there is a large proportion of the equipment that can be changed or altered at small expense and there is considerable leeway in many plants in the manner in which it can be operated, all of which may radically affect the operating economy of the plant.

Oftentimes it will be found that where more than one boiler is installed, more boilers are run than are necessary, simply because the fireman can pile a heavy charge in both boilers at one time and reduce the number of firing periods. At the same time he will be shoveling more coal.

Run Boilers Partly Overloaded

Experience has demonstrated in practice that most boilers can be operated as efficiently, and sometimes at higher efficiency, by running them partly overloaded. In many cases it has been found that a boiler carrying 50 per cent. more load than its nominal rating would evaporate more water per pound of coal than when it was operated at normal load. If a boiler is underloaded it is seldom as efficient as at full load, and in most cases its efficiency is greatly reduced when running below full load.

This is due to the fact that the efficiency of the combustion process is increased at the higher ratings. In many cases the amount of coal burned per sq. ft. of grate surface is as low as six or seven pounds and it is impossible to burn the average run of bituminous coal efficiently at this rate. In a large number of cases the boiler efficiency can be radically increased by increasing the rate to 15 to 25 pounds per sq. ft. of grate surface. This may mean shutting down one or more boilers and a little more frequent firing by the fireman, but he will shovel less coal. Consequently the proportion of boilers to the load will bear considerable investigation in the average plant.

Oftentimes it will be found that the stack is too small for the load, or to maintain the proper intensity of draft for high rates of combustion. In this case the stack will be out of proportion for maximum efficiency, but this can be easily remedied by installing one of the many forced draft fans in the sides of the boiler settings, when almost any desired intensity of draft can be obtained. This is one case where the operator can do a little proportioning himself.

In case only a single boiler is operated and this is too large for the load, the efficiency can be considerably increased by bricking up a proportion of the grate, thus increasing the intensity of combustion on the remainder of the grate. This is another case where the proportioning is strictly up to the man in charge.

In the engine room one will often find two or more compressors dragging along at 30 or 40 revolutions per minute when by speeding up to 65 or 75 and even 85 revolutions for the smaller machines, one or more machines could be shut down, thus eliminating the friction and condensation losses of one or more units as well as the oil and attention required. At the same time the efficiency of the running units at the higher speed will be better than at the slow speed, up to the point where the action of the compressor valves is too slow for the velocity of the piston, which is considerably above the speeds given above.

The same can also be said in regard to brine and boiler feed pumps, water pumps, air compressors and every other apparatus around the plant, including the power engines. Keep them running as nearly as possible at their normal speeds and loads; this will result in maximum economy all around.

Pipes and Coils

When it comes to piping, condensers and expansion coils the man in charge has considerable latitude to demonstrate his ability. A radical reduction in condenser water and power or steam consumption can often be obtained by adding a few more stands to the condenser and prove a gold mine from an investment standpoint. This is especially the case where water is expensive and the fuel likewise; in this case liberal condenser surface is indispensable to commercially economical operation.

In many installations it will be found that many sections, especially of the suction piping, are entirely too small for the volume of gas that has to pass through them, resulting in excessive friction losses and reduced suction pressure, which, in the final analysis, results in reduced compressor capacity and increased cost of operation. Substitution of larger pipe in these cases will pay a handsome return on the investment.

The expansion coils, however, will give the man in charge of the average plant more opportunity to use his discretion and demonstrate his ability, than any other part of the plant. In a great many plants the proportioning of the expansion coils is radically defective and some good judgment in rearranging these, and adding more pipe in a number of cases, will make a marked showing on the operating economy of the plant. This is well illustrated in the article on "Improving a Refrigerating Plant" in the Sept., 1918, issue of "Refrigerating World" and an article by the same writer along similar lines in "Power" recently. Rearrangement and addition of more coil surface resulted in some almost unbelievable economies and brought the overload on the boiler room and compressors down below normal load. Surely a condition well worth striving for, and the condition of this plant was not by any means worse than is the case in hundreds of others all over the country.

Proper Adjustment

Once a plant is properly proportioned, as far as practicable under the existing conditions, the next problem is one of proper adjustment. This, in a way, is as important as proper proportion and entirely up to the man in charge of operation. In the boiler room the thickness of the fuel bed, the damper, or what is the same thing, the draft, the proper water level, and a number of other details should be adjusted to the load and kind of fuel used. Here the man in charge has every opportunity to demonstrate his ability and progressiveness, and make a radical difference in the cost of operation.

In the engine room the adjustment of engine valves, compressor valves, stuffingboxes, bearings, piston rings, as well as the numerous details of various other equipment, including the pumps and air compressors, will make a healthy difference at the end of the year if this is conscientiously attended to. This part of the equipment, however, probably receives more attention than that of the boiler room or those to be mentioned later.

Considerable discretion can be exercised in the adjustment of the condenser

water. In most cases the average man will turn on all the water available and imagine he is doing fine. Where water is expensive to get and fuel relatively cheap, this procedure is liable to prove to be very extravagant at the end of the season's run.

It is generally not a very complicated matter to determine the rate evaporation by the boiler and the amount of steam used by the engine. A simple evaporation test requires no particular skill and will give the relation of pounds of water evaporated to the pounds of fuel burned. The steam consumption of the engine can be approximated very closely from indicator cards, by the use of a steam meter if one is available, or by running the boiler on the compressor alone, on Sunday or some other day when it is not needed for other operations, and the actual coal consumption determined direct. A test can then be run with maximum condenser water running over the condenser and another at the minimum, consistent with highest permissible condenser pressure.

By the latter method, actual operation conditions will be duplicated, and the variations in the steam consumption of the condenser water pump, at the higher and lower output will also be taken into consideration. The cost of fuel can then be compared with the cost of water. If the cost of fuel at high condenser pressure is less than the cost of water to maintain a lower pressure, it evidently is good practice to run at the higher pressure and reduce the cost of operation.

Expansion Valves

It is in the readjustment of the expansion valves, however, that the average man can make some very radical improvements. Some very good articles along this line has appeared from time to time in the "Refrigerating World" and other power plant magazines, and the writer will therefore refrain from discussion of the details in this article. The main point is to keep every foot of expansion coil surface in contact with liquid ammonia and utilize every square foot of surface for evaporation of liquid, without at the same time flooding any one of the coils and throwing a large proportion into the suction line. Liquid in the suction gas simply increases the radiation loss through the suction line and greatly reduces the capacity of the compressor.

To judge the proper setting of the valves, one will have to take into consideration the temperature differences in the various rooms, if direct expansion is used, the size of the coils and their cleanliness. A coil with heavy frost on it will not evaporate the same amount of ammonia as a similar coil with clean surfaces. A heavy coating of oil will act in a similar manner.

However, it is only necessary to watch the suction pressure gauge and experiment with each coil until a point is found where the suction pressure will be maximum without an excessive amount of liquid being carried back into the suction line, as indicated by the frost line on the machine or the thermometer in the suction line, if one is provided. Under these conditions a man will have to keep on his toes in case the temperatures fluctuate in the rooms, as a drop in temperature in any room will reduce the rate of evaporation in the coils in this room and throw some of the liquid into the suction line. Consequently the valves must be pinched off as the temperatures drop and if the suction pressure comes down, in consequence some of the other valves will have to be opened a little more in order to keep them working at maximum capacity.

Cleanliness is another indispensable factor in efficient refrigerating plant operation. This means clean heating surfaces in the boiler room, the regular removal of the soot deposits, thorough washing out of the boiler as frequently as the quality of the water may demand, and the regular removal of scale. A water purifying system will be found a good investment in a number of cases and a turbine cleaner will be found a very good investment where water tube boilers are used.

The same also holds good regarding the condenser. Scale formation on the outside of the pipes on atmospheric condensers and on the inside of the pipes on double-pipe condensers should not be allowed to accumulate. A wire brush on the end of a piece of pipe, run over the pipes occasionally on atmospheric condensers, will wash off a large part of the accumulated sediment and prevent its baking on the coils. On double-pipe condensers, one coil at a time can be cut off from the water circulation and a tube scraper run through it the same as cleaning boiler tubes. Only one or two coils at a time need be cleaned in this manner and by taking a few coils this way every week, or twice a month, the entire condenser can be gone over two or three times every season, which will make a considerable difference in the water consumption and the fuel or power consumption at the end of the year.

The expansion coils in the average plant will require attention along this line more than any other part of the equipment. The dense frost one sees on the average expansion coil is an absolute detriment to efficient operation. Snow and ice is an excellent heat insulator, as arctic explorers will inform us when relating their experiences, and this is just the opposite of what we desire in the operation of an expansion coil.

Thorough cleaning of these coils should therefore be made regularly, depending on how fast and heavy the frost forms. Coils in hot meat coolers or where there is a large percentage of moisture present can be profitably cleaned every day. Others in dry rooms may require cleaning only once a week and in cases only once per month.

If no other method is available, scraping the coils with hook-shaped scrapers will do fairly well, but the hot gas method, described in various articles in the "Refrigerating World," is really the only business-like method of doing this work and the most effective, as it loosens up the oil and brings it out as well as removes the frost from the outside.

Oil should not be allowed to accumulate in any part of the system. For this reason some of the coils should be opened up occasionally for inspection and if any considerable amount of oil is present it should be blown out with steam and air. Any quantity of oil in the coils is just as detrimental as frost on the outside or scale in the boiler tubes.

Tightness of System and Insulation

It seems waste of space to mention here that pistons and valves, as well as the stuffingboxes on the valve stems and pistons of power and compressor engines should be kept tight. The same may also be said regarding air compressors. The fact remains, however, that in a large number of plants there is always a large amount of leakage at these points that would make a sizable coal pile at the end of the year, and the average plant can make some commendable improvements along this line. A steam meter in the line showing the steam consumption per 24 hours before and after making these changes would be an eye-opener for many operators.

Every effort must be made to eliminate ammonia leaks and so much has been said in the various power and refrigerating plant journals on this subject in recent years that it is not within the province of this article to describe the various methods used to locate the leaks and how to remedy them. Suffice to say that regular inspections should be made with litmus paper of the jacket and condensing water and with the sulphur stick on the ammonia joints, especially the discharge line, compressor or absorber and generator, and the condenser. Numerous small leaks, invisible and not noticeable by smell will be found in this manner that will waste large quantities of ammonia in a season's run.

Tight stop and expansion valves are another requisite for economical operation. At 125 pounds pressure a pinhole leak in a steam stop valve will waste a pound of steam every five hours. A few of these leaks in each valve all over the plant will mean an alarming increase in the coal consumption at the end of the season's run. Good valves in the first place, a good reseating machine and renewal of the discs the moment leaks are suspected will mean considerable money saved in the long run. Also considerable judgment can be displayed in selecting the proper disc for the service it is to be used. The discriminate use of every kind of disc for every service as practised in altogether too many plants cannot be too severely condemned; it is not fair either to the plant owner, the disc manufacturer or the maker of the valve. Discs unsuited for the purpose for which they are used will give out in a short time and at the same time ruin the seat of the valve in which they are used.

The Trade and Technical Papers

THE position and business of the trade paper is coming to be more and more recognized by those who have occasion to dig beneath the surface in any particular line, and get down to real facts.

The trade press does not appeal to the mob. It is not a political organ, nor is its purpose merely to entertain. Its mission is to present information along specific lines, to publish the views of men who have succeeded, to give methods and schemes for doing mechanical things the best and most proficient way, to make a mechanic a better mechanic or a salesman a better salesman. In reality the trade paper is the medium through which the man who wants help can get it.

In the Ohio State University Department of Electrical Engineering there is a course in industrial lighting. The literature sent out by the University has the following in regard to the assistance the University authorities are getting from the trade press. Referring to the rapidity with which accepted theories and practices are being scrapped to make room for new ideas, the University letter says:

"One result of this rapid development is that the best available textbooks are to a large extent out-of-date before they are off the press. We are, therefore, confining the work of the course mostly to these letters and to that most up-to-date form of technical literature, the trade publications. We are fortunate in the large amount of good material that is available in the lighting field."

The above reference applies both to the engineering literature sent out by industrial and manufacturing firms and equally so to the technical press of to-day.

In other words, both sources of information are regarded by the Ohio State University as being of more importance than all the textbooks that are coming off the press, because it can keep up to the minute, while a textbook has to stand for certain stated beliefs, even while the procession passes along and leaves those beliefs old and without a following. Again, the University authorities can have no ulterior motive in stating their views on the matter. They are out to secure all the information they can along certain modern problems. They want to bring to bear on their problems every bit of worth-while knowledge they can secure, and their tried experience has been that they find this material in the trade press.

The trade and technical paper is the friend of the man who wants to go farther up, and then men who have succeeded in going farther up are the best friends and most constant readers of the trade and technical papers.

Mental Rust

DID you ever have your fireman, or someone else in your employ, come to you and ask you about some simple point in connection with the plant, or perhaps about some equally simple problem in engineering theory? Of course you have, and you have scratched your head and hemmed and hawed wondering what to say, trying to remember and being exasperated beyond measure at your inability to explain things satisfactorily. It is rather humiliating, isn't it? And yet did you ever count up the years, perhaps, that have elapsed since the textbooks have been opened that still lie on the shelves of the den, or in your office at the plant?

Man's mental equipment may be likened unto a piece of nicely polished shining steel exposed to the elements and with its ever-present tendency to rust and grow dull. And like steel, the only way to keep the memory bright and free from the blight of forgetfulness is to keep polishing, by reading texts, or better still, the more up-to-date contents of the technical press.

Ingenuity Displayed By Native Races

THE possession of a wonderful mechanical sense by more or less primitive races is referred to in an interesting manner by an editorial writer in *The Practical Engineer*, a British publication. Where native labor is employed on engineering works, cases arise where it is wise on the part of the supervising engineer to leave the overcoming of certain difficulties to the solution arrived at by the native mind. Interesting instances of the successful application of this policy are mentioned. There is the case of a dam in Egypt, which was giving trouble through leakage, though the exact spot where the weakness existed was not apparent. A native Egyptian employed on the job conceived the idea of coloring the water on the high side of the dam in order to detect the spot where the leakage appeared on the low side.

The engineering feat we hear of so frequently now of placing the centre span of a bridge by floating it on lighters to its place, and then raising it, was not unknown to the Chinese. In fact it is claimed that it was a Chinese who first utilized the buoyancy of lighters and the help of a tidal stream to place girders in this fashion.

Transporting a Lancashire boiler where there were no roads was encompassed by slinging it bodily on bamboo poles, and manning the poles with enough coolies to carry the weight. Naturally labor was cheap where this method was employed.

Transporting a vertical boiler up a hillside was done by the Chinese headman by means of what we would call parbuckling. The boiler was laid on its side and ropes were passed around it, one end of the rope being made fast to convenient trees, the other end being taken round the barrel of a winch. The winch being started winding in the rope, the boiler naturally rolled up.

This does not seem to us to be nearly so good an instance as the next one, which showed really excellent mechanical thought. This case was of a nine-ton flywheel, which had to be taken to the summit of a hill. Obviously such a wheel was too heavy to take any chances of rolling it up, as one slip would have meant disaster. The Chinese headman was told to get it up, and then left to his own devices. He immediately proceeded to drive strong stakes into the hillside at long intervals, leaving them about three feet above the surface. He then secured some screwed pipe, and screwed a flange on each end of a piece just long enough to fit over the stake. To the top flange he fitted long bars to act as capstan bars. The wheel was then raised by levers, and rollers fitted under it as it lay on its flat. The rope was attached, and the loose end passed around the improvised winch on the stake. Enough men were then placed on the capstan bars, and the order given to heave away. The men walked round and the flywheel came up the hill. When it had reached the stake it was chocked up, the rope let go, and the winch was taken bodily to the next stake. The distance apart of the stakes was limited by the length of the rope available. This was about as safe and quick a way as could have been devised by any one under the conditions prevailing, and was thought out and adopted by a man who had never heard of the principles of mechanics.

The Engineer's Pants

I READ a week or so ago what James E. Noble said about the shiny britches being like a hunk of lead, what's tied around some poor wop's neck to hold him on his job, when he might plan to hurdle out and pasture on green sod.

He says an engineer should have great patches on his knees from kneelin' down to find the cause of every leak and wheeze—that he should have his feet flat out and decked up with a corn, from chasin' round the plant until the blowin' of the horn.

I may be wrong, James may be right, but to my homely view, I love the man whose stern is clad in folds of shiny hue.

I love the man with skillful touch who knows the game all through, who knows just what his plant and coal and stokers three can do—who looks ahead and keeps things sweet like some great Christmas cake, to make them run like grease each day, a-scared, by heck, to break.

To me it is a goodly thing, it makes my heart go thump to hear the rythmed quiver of a nicely-runnin' pump—it makes my spine to have a thrill to see an engine run, without some jay a standin' there with pitchfork and with gun.

It likewise causes me to groan to enter in some place, where engineer has got a streak a campin' on his face. He's crawlin' round the floor, he is, he's camping in the oil. his temper's like a stormy night, it's startin' for to boil.

Sure he has patches on his knees, his feet are sore and flat, he talks like some quack doctor, too, what whispers through his hat. I cannot love this oily jay, nor hold him to my breast, for oil is oozing from his boots, likewise from out his vest.

When I go lookin' for a man to make power for my plants, I'll squint until I find the chap what has the shiny pants, the chap who sits and thinks a bit, who knows just what to do, without a-crawlin' on his knees or sweatin' like a stew. Ah, yes, I'll take him by the hand, and lead him to my place, a smile a-campin' in my soul and one hung on my face. I'll pay to him ten bucks a day, I'll feed him T-bone meat, this chap what has the shiny hue a-glowing from his seat.—ARK.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

Readers are invited to send in answers to these problems, as they have been chosen for their interest and application to the practical side of power plant operation.

Perhaps you, too, have some pet problems, or hard nuts which you would like to ask your fellow engineers; if so, send them along for the benefit of others.

Answers, together with the original question, will be published in the issues following the appearance of the question.

Questions Before the House

80. At what pressure will a safety valve blow off, having a diameter of 4 inches, the weight of the valve and stem is 10 lbs., the lever is 20 lbs., and the ball 120 lbs.? The total length of the lever, which is straight, is 44 inches. The weight is 40 inches from the fulcrum, and the distance from the centre line of the valve to the fulcrum is 4 inches.

81. With a safety valve having the dimensions given in question one, what weight is necessary to have the valve about to blow off at a steam pressure of 100 lbs. per sq. inch?

82. What is the absolute pressure if the vacuum gauge indicates 19 inches, while the barometer stands at 26 inches?

83. Find the quantity of air required to completely burn one pound of fuel of the following composition:

Carbon	84 parts
Hydrogen	5 parts
Oxygen	7 parts
Ash	4 parts

84. How many B.T.U. will be produced by the combustion of one pound of coal of the following composition:—

Carbon	76.5 parts
Hydrogen	4.4 parts
Oxygen	3.0 parts
Nitrogen	1.1 parts
Ash	15.0 parts

85. How many pounds of water at 212 degrees Fah. can be evaporated by 1 pound of the coal mentioned in question 5?

86. A boiler shell 72 inches in diameter is constructed of material. 5 inches thick, which has a tensile strength of 60,000 lbs. per sq. in. What is the bursting pressure, taking no account of the weakening effect of the seam?

87. If the boiler shell whose dimensions are given in question 7 is constructed with a triple-riveted, double-strapped belt joint having an efficiency of 86 per cent., what is the bursting pressure?

88. Find the load on a stay when the pitch is 8 inches either way and the steam pressure 83 lbs. per sq. inch.

89. Staybolts 1¼ inches in diameter are placed 3½ inches from centre to centre. If the steam pressure is 100 lbs. per sq. inch, what is the stress per sq. inch in the stays?

90. A stayrod 2 inches in diameter is cut with a U.S. standard thread and has 4½ threads per inch. What is the diameter at the root of the thread?

91. What working pressure will be allowed on a solid rectangular steel girder 2.5 ft. long, 7 inches deep and 2 inches thick, fitted with three staybolts? The girders are spaced 7 inches centre to centre. The pitch of the stay-bolts is 7.5 inches and the combustion chamber is 30 inches wide.

92. A boiler shell 60 inches in diameter and ½ inch thick, with a tensile strength of 60,000 lbs. per sq. in., has a double riveted longitudinal lap joint, having a rivet efficiency of 68.3%. Under Canadian Marine Rules, what working pressure will be allowed? All rivet holes are punched before bending.

Questions Answered

Question.—64. Explain the difference between outside lap and inside lap of a D slide valve?

Answer.—The outside lap is the amount that the outside edge of the valve projects beyond the edge of the steam port when in mid-position. The inside lap is the amount that the inside edge of the valve projects beyond the edge of the steam port when in mid-position.

Question.—65. Explain the difference, if there is any, between piston clearance and clearance volume?

Answer.—The linear distance between the piston and the cylinder head when the former is at the end of its stroke is the piston clearance. The volume of this space added to the volume of the steam port leading to it is the clearance volume.

Question.—66. Is it possible to cut off with a D slide valve operated by an eccentric, having no outside lap and no lead?

Answer.—With an ordinary D slide valve, operated by an eccentric, there can be no cut-off, and therefore, no expansion of steam, unless the valve has outside lap.

Question.—67. Suppose you had a plain slide valve engine, and you wished to make the cut-off earlier, what would you do? The port opening is to be the same as before.

Answer.—Increase the outside lap, increase the valve travel and the angle of advance.

Question.—68. What is the effect of increasing the inside lap of a D slide valve?

Answer.—The exhaust port will be opened later and closed later.

Question—69. How can the valve be given a greater travel than the throw of the eccentric?

Answer.—By using a rocking arm.

Question.—70. How does the angularity of the connecting rod effect compression?

Answer.—The exhaust port will be closed later on the forward stroke than on the return stroke, and hence there will be more compression at the head end.

Question—71. A 14 in. by 28 in. engine has a clearance volume of 247 cubic inches. Express the clearance in per cent.

Answer.—The volume swept through by the piston is 14 squared, multiplied by .7854 × 28=4,310 cubic inches. Then the clearance is 247÷100: 4,310÷5.73%.

Question.—72. In a 36 in. by 60 in. engine the steam is cut off when the piston has moved over 21 inches of its stroke. The clearance being 2 per cent.; find the real cut-off.

Answer.—The apparent cut-off is 21×100÷60=35%. The real cut-off is (35×2)×100÷100+2=36.27%.

Question.—73. What is the ratio of expansion of the engine given in question 9?

Answer.—The ratio of expansion=100÷36.27=2.76.

Question.—74. A 44 in. by 80 in. engine is to run at 75 r.p.m. What actual diameter of steam and exhaust pipes should be used?

Answer.—The piston speed is 80÷12×75×2=1,000 ft. per min. The area of this piston is 442×.7854=1,520 sq. ins. Area of steam pipe =1,520×1,000÷6,000=233.3 sq. ins. The corresponding diameter for the steam pipe is: —√(233.3÷.7854)=18 in. nearly. The area of the exhaust pipe is 1,520×1,000÷4,000=380 sq. in. Diameter of exhaust pipe —√(380÷.7854)=22 sq. in.

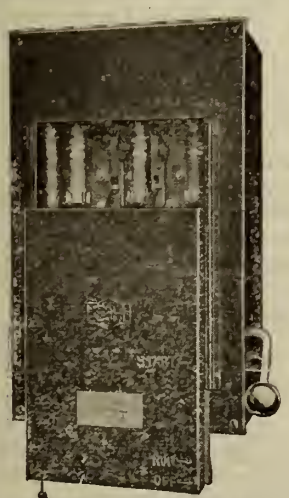
NEW POWER PLANT EQUIPMENT

TWO NEW ENCLOSED STARTERS FOR SQUIRREL CAGE MOTORS

PROTECTION for both the motor and the operator is the main feature of design in the new enclosed starting switches, Bulletins 9117 and 9118, manufactured by The Cutler-Hammer Mfg. Co., Milwaukee.

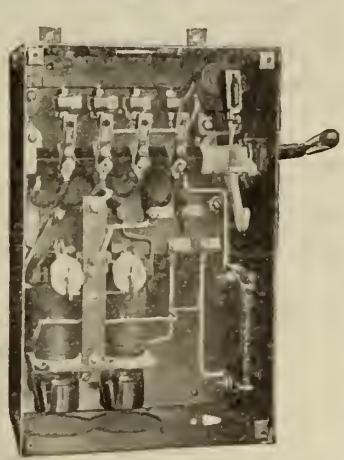
The Bulletin 9117 switch contains an overload protection unit, which is so designed that the circuit is not interrupted by a high initial starting current or by momentary overloads, yet gives protection against the continuance of harmful overloads. This inverse time element action is obtained by the retardation of a plunger in an oil dashpot. The time required for the relay to operate on any given overload condition may be varied by turning an adjusting screw.

The three pole fused starting switch, known as Bulletin 9118, is especially adapted for those motors which cannot be connected directly across the line when starting. A resistor with two sets of terminals allows the motor to be started on either 60% or 75% line voltage. When the motor has reached normal speed, the resistor is cut out of the circuit and the fuses inserted, which is accomplished without breaking the motor circuit. Therefore, the fuses do not carry the heavy starting current, and need be of no greater capacity than to insure proper motor protection.



LOWERING THE PANEL OF THE BULLETIN 9118 STARTER DEADENS THE FUSES AND MAKES THEM ACCESSIBLE FOR RENEWABLE. THE SWITCH CANNOT BE CLOSED WHILE THE PANEL IS LOWERED.

Both types of starters are completely enclosed and are so designed that it is impossible to touch any live parts either while operating or while renewing fuses and making adjustments. The enclosing cases, which are arranged for conduit wiring, prevent the accumulation of dust and grease on the contacts besides protecting the workmen from



BULLETIN 9117 STARTER WITH FRONT COVER REMOVED SHOWING CONTACTORS, DUPLEX RELAY AND LOW-VOLTAGE COIL.

live parts. All contact posts and fingers are of standard C-H drum construction, easily inspected and renewed. Both types of switches are provided with low voltage protection coils.

To operate either type of starter, it is only necessary to raise and lower the handle, which can be locked to prevent unauthorized operation. The starters are made in various capacities for operating squirrel cage motors on potentials not exceeding 550 volts.

SULLIVAN "WAFER" AIR COMPRESSOR VALVES

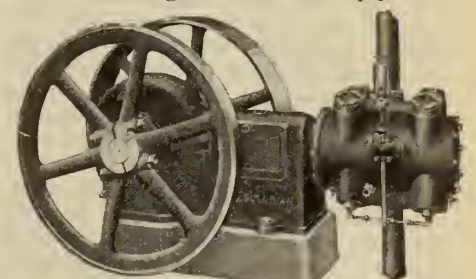
Sullivan Single Stage Belt-Driven Compressors, type WG-6, and the corresponding steam-driven type, "WA-6," are now being supplied with the new improved plate valves, developed by the company's engineers at Claremont, New Hampshire Works. This valve, known as the Sullivan "Wafer" Valve, is shown in the accompanying illustration on this page. The small size, light weight and compactness of the valve and its spring and seat are strikingly illustrated by the other illustration on page 426

As indicated, the "Wafer" Valves seat in cages arranged radially to the axis of the cylinder and close to the two ends of the cylinder, the inlet valve being situated at the bottom and the discharge valve at the top. These valves are held to their seats by flat annular springs of the same material as the valve itself, which is the finest tempered spring steel obtainable. The valves open against specially designed guard plates intended to give a wide port opening with a minimum of clearance volume, and without restricting the admission or charge of the air to or from the cylinder. The valve, spring and guard are easily accessible by the removal of a screw plug.

The simple construction and short compression distance of the springs permit the valves to be located much closer to the bore of the cylinder than is generally permissible with valves of this type, with a corresponding reduction in clearance losses. The light weight of the valves and the superior quality of the material result in long life, and when renewals are necessary, the cost of new valves is a trifling matter. The question of repair stock is simplified because the same valves, springs and guards are used for both inlet and discharge.

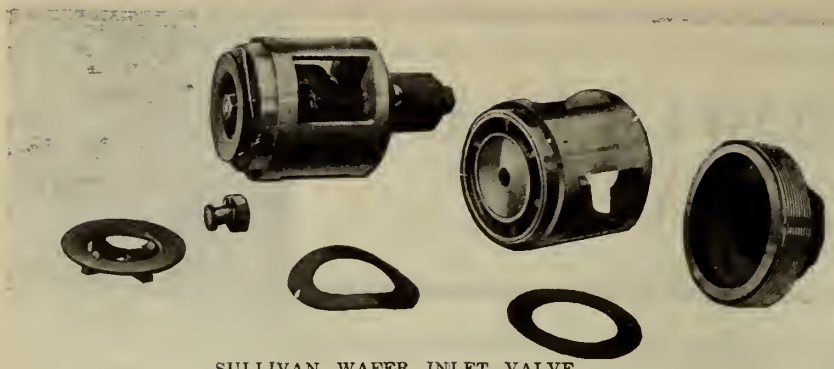
The valves are employed in multiples of relatively small size, rather than using one or two valves of large diameter, the objection to the large valves being the large clearance pockets required and the likelihood of more noisy action and greater breakage.

Compressors equipped with these valves are unloaded in essentially the same manner as the compressors equipped with automatic poppet valves. There is an airpipe connection from the receiver which is controlled by a pilot valve at the side of the air cylinder. When the receiver pressure rises to the unloading limit, the pilot valve admits air pressure through branch pipes to



SULLIVAN "W G-6" WAFER VALVE AIR COMPRESSOR 50-470 CU. FT.

small plunger pistons located in the valve plugs. The other end of the piston carries a three-pronged extension, which raises the inlet valve from its seat until the receiver pressure falls the required amount, upon which the plunger piston falls, the valve seats and the compressor resumes its operation. While the valve is raised and the unloader in



SULLIVAN WAFER INLET VALVE.

action, no air is compressed, the piston of the compressor simply carrying the air at atmospheric pressure through the cylinder and open valves.

Sullivan "Wafer" Valves have been in use for several years with great success on high pressure compressors supplied the United States Navy for charging torpedoes at pressures ranging as high as 2,500 pounds per square inch. In this service their durability, power economy and ability to maintain a tight seat after long use and the reliability of the special springs, which have been developed for this service, have all been amply demonstrated.

STEAM ENGINE VALVES

By R. S. Wright

By keeping the following rules handy they will help to solve many of the problems applying to the steam engine:

1. With an ordinary D slide valve, operated by an eccentric, there can be no cut-off and therefore, no expansion of steam, unless the valve has outside lap.

2. Increasing the outside lap means an earlier cut-off and an increased expansion, while decreasing the outside lap means a later cut-off and a diminished expansion.

3. Increasing the inside lap causes the compression to begin earlier in the stroke and causes the release to take place later. On the other hand, diminishing the inside lap causes the compression to begin later and the release to begin earlier in the stroke.

4. When the valve rod and the eccentric rod moves in the same direction with an ordinary slide valve, the eccentric is set ahead of the crank, and the angle between the crank and eccentric is 90 degrees plus the angle of advance. This law is true whether the engine runs over or under.

5. In the case of the plain slide valve, if a rocker-arm is so pivoted as to make the valve rod and eccentric rod move in opposite directions, the eccentric must be placed behind the crank, and the angle between them is 90 degrees, minus angle of advance.

6. When an indirect valve is used, set the eccentric behind the crank and make the angle between them equal 90 degrees, minus the angle of advance. If a rocker-arm is used that makes the valve rod and the eccentric rod move in opposite directions, set the eccentric ahead of the crank, and make the angle between them equal to 90 degrees, plus the angle of advance. This applies whether the engine runs over or under.

The Effects of the Connecting Rod on Steam Distribution

7. It will cause the valve to cut-off and release the steam, as well as close the exhaust port later on the forward stroke of the piston than on the return stroke.

8. To find the real cut-off, add the clearance volume expressed as a per cent. of the stroke, to the apparent cut-off expressed in per cent., and multiply the sum by 100, divide the product by 100 plus the clearance volume in per cent.

9. To find the area of the steam pipe leading to an engine or pump, multiply the area of the piston by the piston spread in feet per minute, and divide the product by 6,000.

10. To find the area of the exhaust pipe, or exhaust port, for an engine or steam pump, multiply the area of the piston by the piston spread in feet per minute and divide the product by 4,000.

11. To find the area of the steam port, multiply the area of the piston by the piston speed in feet per minute; divide the product by 7,000 if the port is short and direct, and by 6,000 if the port is long and tortuous.

Questions Answered

Continued from page 424

Question.—75. About what scale of spring is usually selected for a given boiler pressure?

Answer.—About equal to one-half boiler pressure.

Question.—76. What is the principal objection to the lazy-tongs and pantograph reducing motions?

Answer.—Their joints are apt to become loose and thus distort the diagram.

Question.—77. What is meant by the vacuum line on an indicator diagram, and how is its position located?

Answer.—The vacuum line is the line of no pressure and is located below and parallel to the atmospheric line at a distance equal to the atmospheric pressure divided by the scale of the spring used to make the diagram.

Question.—78. In plain slide valve engine, how would you remedy too early admission, and what effect would this have on the other events of the stroke?

Answer.—Decrease the angular advance of the eccentric. This would cause cut-off, release, and compression to take place later.

Question.—79. If one end of a cylinder with a slide valve is found to be doing more work than the other, how can the fault be remedied?

Answer.—Change the length of the valve stem so as to make cut-off earlier on the end doing the greater amount of work.

NEW UNION OF STATIONARY ENGINEERS AND FIREMEN

The Canadian Brotherhood of Stationary Engineers and Firemen has recently been organized in Edmonton, with J. Antrobis general secretary. This new organization is very broad in its scope and includes oilers, pumpmen and helpers as well as others connected with the craft.

SULLIVAN WAFER DISCHARGE VALVE.

A Dominion charter has been applied for, and it is expected that headquarters will be in Edmonton.

The Department of Electrical Engineering, Ohio State University, have issued a series of technical letters on Industrial Lighting. These letters have been developed in connection with an extension course carried on by the university. While the earlier technical letters are of an elementary character, making their greatest appeal to those who are not familiar with the science of illumination, most of the letters of the series contain information of value to the illuminating engineer. A departure has been made from the practice of using the standard text book as a source of inspiration, and recourse is had to the medium of trade literature and the columns of the technical press for up-to-date information on the various subjects studied. For those wishing to make a study of the science of illumination the extension course, of which these letters form a part, is to be commended.

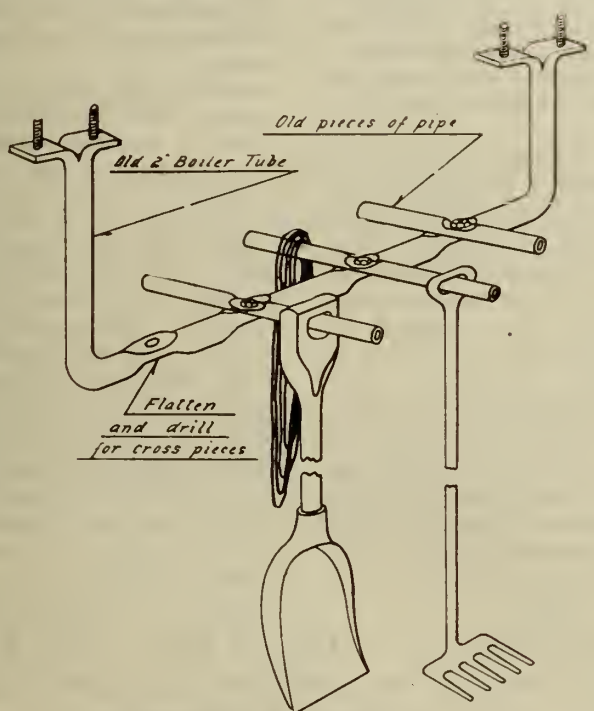
The Yarnall Waring Co., Chestnut Hill, Philadelphia, have issued a new list of users of the Yarway (formerly the Simplex) Seatless Blow-off Valve.

The Operators' Point of View

BOILER ROOM TOOL RACK

By CHAS. H. WILLEY

Old junk and spare time are easily turned into useful contrivances that make into the boiler room of a small plant in the plant more attractive and a better place to work in. Recently, I stepped Boston, Mass., and noticed the water tender has constructed a very handy fire



BOILER ROOM TOOL RACK.

tool rack. I sketched it out roughly and pass is along. It was made from an old 2-inch boiler tube and some short lengths of 1 inch. The hanger feet were made by splitting the ends of the tube, flattening out and bending back. The cross pieces are secured by flattening a section of their centre and drilling for bolts.

BOILER WATER TREATMENT

In POWER HOUSE of August 20 there is an article on the above subject which appears to contradict the results of other experiments, although the apparent contradiction may be explainable.

It is stated in the said article that soda ash, after a long series of experiment, has apparently been shown to produce brittleness in boiler steel, but it is not stated who conducted the experiments.

A series of experiments conducted by the University of Illinois Engineering Experiment Station on the embrittling action of sodium hydroxide (caustic soda) on soft steel, resulted in the following finding: "In general there seemed to be sufficient data for concluding that: (a) Caustic soda of sufficient strength attacks iron with the generation of hydrogen. (b) Hydrogen in the nascent state, whether generated by alkali or acid, enters into the texture of the iron in a way to modify its physical properties. (c) The hydrogen effect, at least in its first application, is transient, and after a period of rest or freedom from the hydrogen action, the iron reverts to its normal condition. (d) Sodium carbonate (soda ash or sal soda) is without action on iron; there is, therefore, no generation of hydrogen."

It would appear, from these experiments, that soda ash is perfectly safe to use. It is explained, however, that by the use of soda ash sodium hydroxide may be formed under certain conditions.

These conditions may be removed by the use of an open feed water heater in which the water will be heated to 212° Fah. with the result that carbonic acid gas is eliminated, and if the filtering capacity of the heater is sufficient, the carbonates of lime and magnesia will also be removed.

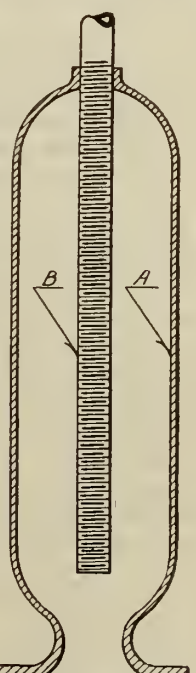
In connection with the open feed water heater, it might also be stated that the proper place to introduce the compound is after the water has passed the heater, when there will be only the sulphates to treat.

Possibly some other reader of POWER HOUSE has ideas on the matter, and can help us to learn more and earn more.

R. McLaren,
160 Dovercourt Rd.

CONNECTION TO AIR CHAMBER

This sketch indicates how someone connected the water discharge pipe to the air chamber of a pump. What the idea was I do not know, unless it was to economize in space or reduce the number of pipe fittings used or else avoid the friction of sending the water through one or two elbows as the water was being delivered to a point directly above the pump. By putting a long thread



PUMP AIR CHAMBER.

on the discharge pipe it was possible to insert it far enough into the air chamber to still have the advantage of an air cushion therein.—J.E.M.

A STUDY IN FUEL ECONOMY

Showing the Saving Possible by Proper Insulation

Steam production is essentially a wasteful process. At the very best,

we cannot hope to get anywhere near 100 per cent. efficiency out of the coal we burn. And without modern appliances for correct firing we cannot hope to approximate anywhere near this figure.

This is all the more reason why we should take care of this costly heat, every step of the way, from the time it is fed as coal into the hopper of the underfeed stoker until the last few B.t.u. are used up in the feed water heater.

Heat is far more evasive than gas. It leaks through a steel boiler plate or steam pipe, like water through a sieve. It leaks through unprotected valves, flanges and fittings—always seeking to level up its temperature to that of the surrounding air.

Steam at only 100 lbs. pressure has a temperature of 388° Fahrenheit, while even the hottest summer day will rarely exceed 90°, so that it takes only a moment's thought to realize the enormous leakage that can take place from even a few feet of uncovered or imperfectly covered pipe.

Steam Pressure.	100 lbs.	150 lbs.	200 lbs.	200 lbs. 100° Superheat
B.T.U. loss per hour per sq ft. bare pipe	802	937	1058	1735
B.T.U. saved per hour, pipe covered with proper insulation	676	795	905	1525
Tons coal saved per year, per 1000 feet of pipe so covered	270	218	362	565

Coal efficiency 14,000 B.T.U. per lb. Boiler efficiency 70%. Thickness of insulation 1 inch. 1 ton = 2240 lbs.

Above are some startling figures recently compiled from tests by the Mellon Institute of Industrial Research. Pittsburgh. They show in graphic form the actual fuel loss on bare pipes as compared with pipes covered with a good insulation.

Following are some figures compiled by the engineering department of one of the largest manufacturers of insulation in America. A 6" pipe conveying steam at 100 lb. pressure through even a hot boiler room with air between 80° and 90° Fahrenheit, will lose, if bare or uninsulated, 1,278 B.t.u. per lineal foot per hour. When the proper insulation is applied, two inches in thickness, on a 6" pipe, there is a saving in B. t. u. of 91.3%. This saving amounts to 1,166 B. t. u., or in other words, the loss by applying two inches of insulation is reduced from 1,278 to 112 B. t. u.

The subject of heat insulation is somewhat imperfectly understood, even by many of our best engineers.

The real object of insulation is to prevent the flow of heat to the outside air from the pipe through which it is being conveyed. The efficiency of an insulation is expressed by a percentage, which is the per cent. of heat saved by using the insulation as compared to what would be lost if no insulation were used and the pipe left bare or uninsulated. The efficiency of all insulations varies according to the size of pipe to which they are applied and according to the difference in temperature between steam in the pipe and air surrounding the pipe, as well as according to thickness of insulation.

It cannot be too strongly emphasized that every unprotected piece of metal in a steam system is a heat thief. Thus "one pair of ten-inch flanges will waste a ton of coal a year." It doesn't take much figuring on that basis to prove that there is an enormous amount of valuable heat going to waste.

Not every "pipe-covering" is a good insulator. There are some that are effective at low pressures, but useless for the higher temperatures. Others are good when first applied but soon deteriorate with the constant heat. Others again are frankly "made to sell." The trouble is, they all look alike on the pipes.

Whereas, in the early days of steam, hay, hair, wool, feathers and other materials of animal and vegetable origin, were freely used, the choice to-day for high temperatures is limited to a few non-organic materials of which perhaps the best known are the two described below.

The first, consists specifically of a mass of crystalized magnesium carbonate, in the substance of which is securely enmeshed a myriad of microscopically small dead air cells.

The second, is made up of layers of thin felt composed of asbestos fibre and particles of finely ground, spongy material, which contain a large number of very small enclosed air cells. These layers form an extremely cellular felt, built up like a book in laminated form, thereby confining a large volume of minute dead air cells both in the felt and between the layers.

It is this basic principle of "dead air" in microscopic subdivision that is vital to the efficiency of any heat insulation.

Air that circulates is an uncommonly good conductor of heat. Stagnant air is one of the poorest conductors. Thus, the more dead air cells per cubic inch of the covering, the greater its efficiency.

The test of the weight alone will always decide this question, always remembering that large air spaces, permitting heat loss by convection, are not suited for any but low pressure heating systems.

Never wrap a pipe with asbestos paper before applying insulation as it is a waste of time and money. If the insulation is any good at all it will safely withstand all the heat it can get.

It is well worth while finding out not only that your pipes, valves, flanges and fittings are covered, but that the covering is ample for the service demanded. If they are hot outside the covering, it is certain they are losing heat, and your covering is either unsuitable or insufficient.

Cover your feed lines as well as your exhaust. Protect your boiler walls and breechings as well as the tops. There is no real reason why your engine room or boiler house should be excessively hot at any period of the year. It merely means you are warming "all outdoors" instead of carrying your heat where it is most needed.

Heat leakage spells total loss, just as surely as does poor firing. It spells unnecessary overhead costs that may some day help to lose you a big order. It is as unnecessary as any other form of waste and just as easy to cure.

In selecting an insulation, be sure and pick a covering that is pliable, will readily conform to the surface it covers, stand pipe, vibration, expansion, and contraction, will not pulverize or break away, and when subjected to excessive moisture. will dry out and regain its initial efficiency. This and its heat resisting qualities. mechanical ability to withstand everyday wear and tear, cover the important points which should be taken into consideration when selecting the proper insulation.—"The Combustion Chamber."

Some Notes on the Theory of Heat

By T. H. FENNER, Extra Chief Engineer, M.I. Mar. E., London.

AS the steam engine, the Diesel engine and the steam turbine are all heat engines, is is necessary for the student of marine engineering to get a firm grasp of the theory of heat. When this is understood its application in the various forms of marine and other engines can be readily understood.

To begin with, the student must learn to disassociate the terms temperature and heat. To the average man, the one term means the same as the other, but to the engineer there is a distinct meaning to each.

Sensible heat, or temperature, is heat that is capable of being measured on a thermometer, or in other words, that can be appreciated by the sense of sight. The temperature of a room, the water that we drink, or the flame of a fire can be felt, and can be read on the scale of a thermometer, but heat itself can neither be seen nor felt.

Before the present scientific theory of heat was accepted, heat was supposed to be a substance, but research and experiment have proved that heat is a form of energy or motion.

Since heat is a form of energy, and as such can be employed to do useful work, we must have definite units by which it can be measured. The unit of work is a foot pound and is the amount of work which is performed when a weight of one pound is raised one foot. This is not affected by the rate at which the work is perfomed. It does not matter if it takes one second, one hour, or one year. The actual work is one foot pound.

The unit of heat, or, as it is commonly called, the British thermal unit, is the amount of heat required to raise one pound of fresh water one degree in temperature when at its maximum density, that is from 39 degrees to 40 degrees Fahrenheit.

Now, clearly, if there is a definite relation of work to heat there is a definite relation of the units of one to the units of the other.

Although many investigations and experiments have been made, the unit determined by the famous Joule is the accepted one, though it has been modified slightly by later experiments. He found that the mechanical energy required to raise one pound of water one degree was 772 foot pounds. This has since been modified to 778 foot pounds, which is the accepted standard at the present day The student can find the experiment described in detail in almost any good book on elementary mechanics or steam. This unit has been named Joule's equivalent, in honor of the investigator.

The Nature of Heat

Heat can be transferred from one body to another, and in so doing affects the body to which it is transferred in one of two ways—it either increases the temperature of that body or changes its state, and the body from which it is transferred is lowered in temperature or has its state changed. It may both raise the temperature and change the state of the body, but the one effect precedes the other, and between the two we get the phenomena of latent heat.

Latent Heat

Latent heat is so called because its effect is not apparent to the senses, but is absorbed in the substance which it enters, its only effect being to change its state. It is this latent heat which is the most important to engineers, because it is the energy stored up in it that enables them to utilize the expansion of steam to perform useful work in an engine or turbine. It is also the latent heat of ammonia, carbon dioxide, and sulphur dioxide which makes refrigeration a commercial possibility. It is most important that the properties of latent heat should be thoroughly understood.

If we take an open saucepan and fill it with water, and hang a thermometer over it with the bulb in the water and place it over the fire, the temperature as shown by the mercury will rise. This rise will go on until the mercury shows 212 degrees on the Fahrenheit scale. If the water had a temperature of 40 degrees when we placed it on the fire the amount of heat transferred to the water would be 212 —40=172 units for every pound of water in the pan. Suppose the pan held 10 pounds of water, we should have 720 heat units. or British thermal units. commonly called B.t.u.'s. Now if we allow the water to boil away, keeping the bulb of the thermometer in the water as it goes down until none remains, we should still find that the thermometer reads 212 degrees. Clearly, if the heat has been going into the water all this time we must have added a considerable number of heat units. but all we have to show is the same reading. All the heat added since our themometer reached 212 degrees has been absorbed in making the change from water into steam. It has become latent heat, and the number of heat units required to change one pound of water to one pound of steam at atmospheric pressure is 966.6, therefore the total number of heat units required to change our 10 pounds of water at 40 degrees Fahrenheit and at the pressure of the atmosphere to 10 pounds of steam at 212 degrees and the same pressure would be (212—40+966.6) +10=10,386 B.t.u. This amount of heat represents a mechanical energy of 10386×778=8,080,308 foot pounds. If this work was done in one minute the equivalent horsepower would be 8,080,308÷33,000=244.8 h.p. Let us take a further illustration. Suppose we have a block of ice weighing ten pounds, and we place it in a refrigerator, the temperature of which is above the freezing point, 32 degrees Fahrenheit. Instead of allowing the water to drip away as the ice melts, catch it all in a pan, and when the ice has finally melted, read the temperature of the water. It will be found to be immediately after melting the same as the ice was before melting, but the temperature of the refrigerator will have lowered. What is it that has lowered the temperature? It is the heat that has been absorbed into the ice to change its state from a solid to a liquid, and is 140 B.t.u.'s for every pound of ice changed into water. In other words, if this amount of ice had been melted over a fire you would have had to transfer 1,400 B.t.u.'s into the ice at 32 degrees to get ten pounds of water at 32 degrees. From this we get the latent heat of ice and water at atmospheric pressure, 140 and 966.6 respectively.

The foregoing constitutes what is known as the first law of thermo-dynamics, and is stated as follows:

Heat and work are naturally convertible, and heat requires for its production and produces by its disappearance. mechanical energy in the proportion of 778 foot pounds for each unit of heat.

MORE POWER PLANT AND OTHER KINKS

By J. E. MacCormack

For making small mechanical drawings or rough shop sketches, as for instance of a broken or worn unnumbered part which is to be replaced, a two-foot four-fold drawing rule (the type which is six inches long when folded, can sometimes be used to serve the purpose of an absent T-square. On a sheet of paper 8½ by 11 a fair sketch of 6 by 6, or even larger, may be made on one corner by means of the rule and a pencil. The rule is opened to right angles by setting it to the angle of the corner of the paper. Then for drawing lines, hold the rule by the same sections you are using as a ruler and keep the other sections even with one side or one end of the paper. This gives parallel lines two ways and to some extent the figures and graduations on the rule may be made use of in determining the distance apart and the length the lines should be to give the required proportions. If the rule is stiff in the joints it will keep its right angle position, or, if loose, a pin or tack flattened and pushed into the hinge may tighten it enough to hold so long as the rule is not held by one leg while the pencil is bearing against the other in lining.

For drawing ink lines with a common pen this also serves better than a ruler lying flat, since the pen nib need not touch the ruler and therefore does not ink it, and the six-inch projection at right angles prevents any tendency to the rolling motion that would be present with a flat ruler held on edge for the same purpose.

In the event of an engine running away because of an accident to the governor belt when the engine is equipped with only a slow-acting screw throttle, or a globe valve for a throttle, and is not equipped with an automatic engine stop, then a few seconds difference in the time of getting acceleration prevented may make the difference between little harm done or having a wreck. The operator may sometimes save a few seconds by giving attention to the governor first and utilizing it as a sort of lever throttle to prevent further acceleration until he can get the slower screw throttle closed. With the ball and lever type of governor he can raise the lever arm until the valve comes to a position where it will shut off most of the steam, thus preventing further acceleration. With the smaller sizes of engine he can generally reach the throttle and close it while holding the governor. If the engine does not permit of this it should certainly be equipped with a reliable automatic engine stop. With the ball and lever governor it will not do to raise the lever too lest the valve be passed too far past its seat and there be difficulty in getting it back again. To avoid this, something could be firmly fixed above the engine and extending downward in such a way as to nearly touch (within ½ in. or 1 in. if the valve will permit without catching) the governor lever when the engine is running at normal full speed. The object of this is to prevent the operator raising the lever too far by hand. With the globe valve type of throttle, if the hand wheel be replaced by a heavier wheel having a balance wheel action, the valve may be closed more quickly in an emergency, but there is some danger of jamming the valve face. If the operator practices the above-suggested method of shutting off steam when he is stopping, anyway, he will be less apt to get confused in attempting it in emergency.

The town of Hanley, Sask., want tenders which will be received up till Sept. 24th, 1919, for the supply of the following machinery One internal combustion engine, generator, exciter, switchboard, transformers, meters. The supply and delivery of poles, erection of pole lines, and erection of power house. Plans and specifications can be obtained from the consulting engineers, Murphy & Underwood, Saskatoon, and the Secretary-Treasurer, Hanley, Sask.

Farnsworth Condensation Pumps

Farnsworth Condensation Pumps offer a double saving through their closed system of keeping the Condensate under pressure and returning the maximum number of heat units to the boiler at the same time operating on a small friction of steam required to operate a reciprocating pump.

This feature of Condensation Pumps is sufficient to recommend them for your consideration when making a replacement. This type of pump and steam trap are fast gaining favor in plants where pumps are employed.

Let us tell you how these pumps are operating in other large Canadian Plants.

MARINE BOILER LOGIC

The Heine Safety Boiler Co., St. Louis, Mo., has just completed the printing of "Marine Boiler Logic," a 69-page booklet dealing with the fundamental design of marine cargo carriers. The booklet was written by Chas. H. Stoddard, consulting marine engineer of the Heine Company.

The main part of the booklet relates to the design and construction of Scotch and water tube boilers for marine purposes. Evaporative capacities are worked out for the two types, using coal or oil as fuel, with natural or forced draft. The booklet contains also a discussion of power and speed of cargo vessels, formulas being developed showing the relation between boiler and prime mover capacity, and the dimensions of the hull. In making these computations, the method developed by Rear-Admrial D. W. Taylor of the United States Navy has been used with certain modifications suggested by Mr. Stoddard's experience.

The last part of the booklet is devoted to a description of the construction and operation of the cross-drum type of water tube boiler developed by the Heine Company for marine service.

Folder on Ash Conveying

"Have you ever counted the cost of moving ashes from boiler plant to bin or pile?"

That is the "pertinent ash pile" question the American Steam Conveyor Corporation, of Chicago, are asking their prospective customers in the latest folder put out by this concern.

This folder advances in a logical way arguments favoring the use of an American Steam Ash Conveyor in power plants, and shows the savings that can be accomplished through its use.

McCutcheon, Ferguson and McCutcheon, Sarnia, have ordered from the Frick Ice and Refrigerating Co., Montreal, one nine-ton refrigeratring machine of the enclosed type, belt driven. This, with the room piping also ordered, will be used in their cold storage plant.

Trade Commissioner H. G. McLean, at Rome, writes of new metal alloy of zinc and copper which has been given name of Biakmetal. This alloy quickly demonstrated its usefulness in Italian industry, and by reason of its special qualities promises to attain similar success throughout world. It is stronger than steel and less corrosive than copper.

TRADE GOSSIP

Finished Shop.—In St. Thomas the M.C.R. have just completed new shops of very fine construction.

Grant to New Industry—The property owners of Cobourg have voted in favor of a by-law to grant the Douglas Packing Company $5,000 towards securing an adequate supply of water for their new plant. The plant consists of five new buildings erected on the site of the old steel works.

Coal Mine Re-Opens.—The Dominion Coal Company has opened the New Victoria Mine at Sydney, N.S. This mine was closed down as far back as 1902, and was re-opened in 1913, but was closed down again at the outbreak of war in 1914. At the time it was closed down in 1902 the mine had a capacity of 1,800 tons per day and employed about 400 men.

Ottawa Employment Statistics.—According to reports from the Employment Service of Canada at Ottawa, there is no serious unemployment in the Dominion. The Government employment officers all over the country were placing on an average of 10,000 workers per week, and during the harvesting rush this number was increased to 12,000. The total number of applications from March 1 to August 23, was 190,455. During the same period 201,785 positions were offered by employers, and 139,492 persons were placed in positions. The service moved 15,000 workers to the West for the harvest, and made it unnecessary to import labor for this purpose.

PERSONALS

The death is announced from Trenton, of Robert Weddell, the prominent harbor contractor. Mr. Weddell was well-known in Toronto, and was the contractor for the Western entrance to Toronto harbor. He also was successful in bringing in the intake pipe after the Works Department had made several unsuccessful attempts. He was a personal friend of Mayor Church and George Wright of the Walker House. He leaves a son.

Mr. Ignace Schilowsky, consulting engineer with the Youroveta Home and Foreign Trading Co., 165 Broadway, New York, has been spending some days in this district. Appointed by the first provisional government following the revolution in Russia in 1917, Mr. Schilowsky came to America with the Russian ambassador. Of course the present Government in Russia does not recognize any of these appointments, and so it is that the Russian legation of that time is now interesting itself in preparing for the development of mineral deposits in Russia as soon as conditions there will permit. "Before the war," stated Mr. Schilowsky, in discussing Russian mineral wealth, "the country was supplying much of its own copper, using up-to-date methods, although financed by foreign capital. Iron ore in Southern Russia is also found very near to large deposits of suitable coking coal. The development of these deposits was undertaken largely by French and Belgian capital." The new developments will take place in Siberia, where there is potential wealth. The Irtysh Corporation, financed by English people, has already done much here, and will proceed again as soon as the people in control there decide in which direction they are going. During his stay in this country Mr. Schilowsky has visited the Shawinigan plant, Montreal, asbestos mines in Quebec, Ottawa, Sudbury, Toronto and Niagara, being especially interested in water power development and the various methods that are used in treating metals in this country.

DRAUGHTSMEN'S ASSOCIATION

It is not, perhaps, generally known that there is in Canada an organized Draughtsmen's Association with headquarters in Toronto.

This society was organized on May 16, and on the second and fourth Friday of each month hold regular meetings in the Sons of England Hall at 6.30 p.m.

We understand that the main objects of this association are to promote the economical and intellectual welfare of the class, to encourage intercourse between all draughtsmen, to facilitate the acquirement and interchange of professional knowledge among the members, also to bring about a better understanding between employers and employees, and to procure the means of securing employment and supplying help. The president of the association is Mr. Geo. H. Rix, of the Canadian National Railways; the secretary is Mr. Arthur E. Fetherstonhaugh, architect, 234 Kingswood Road, Toronto, to whom all communications should be addressed.

The Belt Grip Pulley Company of Canada, Ltd., has been incorporated to carry on business as manufacturers of all kinds of pulleys and wheels. The capital stock is $200,000, divided into 20,000 shares of $10 each, the head office being in Toronto.

Japs Have Trouble:—T. Hiroto, managing director of Ocean Transport Co. of Kobe, Japan, announced in San Francisco that owing to excessive costs of ship construction in Japan, and the inability of Mikado's builders to accept and turn out orders, Japanese are planning to come to San Francisco to have additional tonnage constructed.

CANADA HAS 26 958,411 CUBIC FEET COLD STORAGE SPACE

The following, from a summary of an address on the subject of Cold Storage Facilities in Canada, delivered by Mr. J. A. Ruddick, Dairy and Cold Storage Commissioner, Department of Agriculture, before the select standing committee of the House of Commons on Agriculture and Colonization, is taken from the August issue of the Agricultural Gazette of Canada, published monthly by the Department of Agriculture:

"There should be ample storage facilities for the handling of dairy produce and meats in the localities where these articles are produced. The abattoirs of the country provide their own facilities for the chilling or freezing of meats as the animals are slaughtered. The largest cheese factories and creameries are also fairly well equipped in this respect. There is also required good refrigeration car services with a sufficient number of cars of the right type to carry the products in proper condition. For the export meat trade there are also required terminal warehouses where refrigerator

cars may discharge their freight close to the ocean berths. We also require suitable refrigerator space on the steamers if our overseas trade in perishable food products is to be fully developed.

Cold Storage Warehouses

"There are about 190 cold storage warehouses in Canada. All of these warehouses are equipped with mechanical refrigeration, except a few very small ones in which the crushed ice and salt system of refrigeration is used. Not including the smaller plants used in connection with retail shops, we have in Canada a total of 26,958,411 cubic feet of refrigerator space. There are also quite a large number of smaller private storages running from about 2,000 cubic feet to as high as 20,000 cubic feet capacity. These provide about 758,000 cubic feet of space, making a total of 27,717,211 cubic feet available for cold storage of meat, fish, dairy, and other products.

Refrigerator Cars

"The several railways of Canada have a combined total of 4,459 refrigerator cars, made up as follows:

Railways	Ordinary cars.	Brine tank cars
Canadian Pacific	504	1,931
Grand Trunk	965	200
Grand Trunk Pacific	39	195
Canadian National	*625	
Total		4,459

*Kind not specified.

"The Canadian Pacific Railway has also 100 cars equipped for use on express trains.

Terminal Warehouses

"The cold storage warehouses at Montreal, Que., and other places fill the requirements to some extent. They meet the needs of the dairy produce trade fairly well except in the matter of economical handling. A large cold storage warehouse now under construction by the Harbor Commissioners at Montreal will be situated on the docks, will have track connections with all the railways, and will have at least one steamer berth where goods can be loaded direct. The location is very central, being close to present produce district. Provision will be made for unloading directly from the cars into the warehouse and from the warehouse direct to the steamers. This warehouse will have a total capacity of 2,000,000 cubic feet, and will cost in the neighborhood of $1,500,000.

Ocean Refrigeration

"Until overseas transportation becomes normal again there may be some shortage in refrigerated space for trans-Atlantic shipments. Before the war there were forty-five steamers with refrigerated space sailing from Canadian ports to the United Kingdom and four to South Africa, with a total refrigerated capacity of 1,072,476 cubic feet. There were also eighteen steamers equipped with 800,000 cubic feet of cool air space suitable for cheese, bacon and apples. For the current season the indications are that there will be only twenty steamers as against forty-five going to the United Kingdom and one against four to South Africa, having a total refrigerated capacity of 375,212 cubic feet of space which is less than one-half of what was available before the war. Ten steamers are equipped with cooled air compartments, with a total of 159,800 cubic feet capacity, as against 800,000 cubic feet before the war. The shortage is accounted for by the sinkings by submarines and the present use of boats carrying large accumulations of meats and dairy produce from Australia and New Zealand.

"The Department of Agriculture, through the Dairy and Cold Storage Branch, undertakes the inspection of refrigerated cargo on ocean steamships sailing from Canada. This service has been in operation since 1900. A number of inspectors are stationed at Montreal to watch ships being loaded with perishable products, chiefly of those kinds that are carried in refrigerated space. Thermographs are placed in different parts of the ship where perishable products are carried. These instruments automatically record the temperature continuously during the voyage. When a ship arrives at a United Kingdom port another inspector secures the charts and thermographs and returns them to Montreal. Copies of the charts are made available to any person interested in the shipments. The Dairy and Cold Storage Branch has records covering practically every shipment that has been made for the last twenty years."

ENGINEERS WANTED

To sell locally for firm of mechanical and electrical engineers, and secure inquiries for firm handling pumps and general power apparatus, on commission basis. Address

MACLEAN & BARKER
128 Bleury St. Montreal

WANTED — A FIRST-CLASS EXPERIENCED operating engineer, to take full charge, and be capable of managing Water Works Plant in Ontario City, with High Duty Pumps, also Steam Turbine and Electrically Driven Motor Pumps, with Staff of Operating Engineers and Firemen. None but thoroughly competent man need apply stating experience and reference. Address Box 150, Power House, Toronto.

BOILERS FOR SALE

ALL IN EXCEPTIONALLY GOOD CONDITION —17 Atlas Horizontal Tubular Boilers (Babcock & Wilcox), 60 inch by 16 feet, with Jones Underfeed Stokers: Boilers lying at Kitchener. 1 350-H.P. Erie City Boiler. 4 250-H.P. Scotch Marine Boilers with wet heads, now lying at Wallaceburg plant.

Save ⅔ Your Steam Trap Costs with a SARCO !

For about one-third the price of a bucket or float type of steam trap, you can get the Steam Trap Sarco—a compact, simple trap of improved type that does the same work as the more cumbersome and expensive kinds.

It has only one moving part. No levers, gauges, stuffing boxes, etc., to get out of order or need constant adjustment.

The Sarco operates automatically and dependably by the opening and closing of a valve controlled by a sensitive, but *absolutely reliable* expansion element. It allows no condensation to gather in the pipe. It wastes no steam. It does not leak.

Because of its small size, you can install a Sarco in the most limited space at any point on the line, at any angle, without change of piping. Requires no building up, no supports, no floor space.

It is guaranteed for any given pressure up to 200 lbs. Made in sizes ⅜" to 3".

Don't pay three times as much as you need to for a steam trap.

Let us send you the Steam Trap Sarco for a 30 days' trial, free of cost or obligation. Booklet "J" on request.

SARCO COMPANY, Inc.

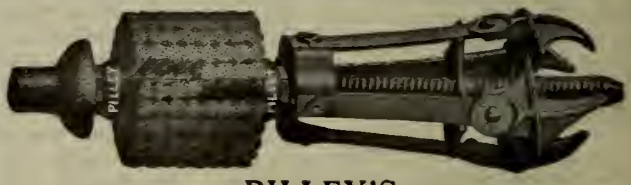
The Simplest and Best Cleaner on the market is



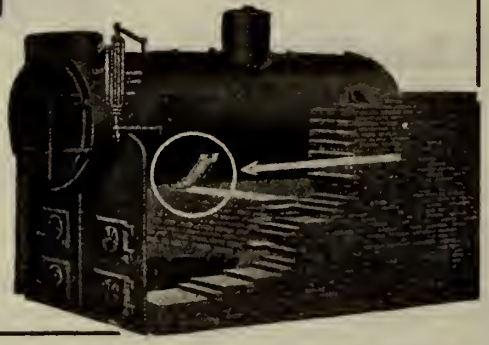
PILLEY'S

Combination Flue Brush and Scraper.
Guaranteed not to break or the wires to pull out or lay over. A simple turn of the hand adjusts it to the tube, and the brush removes what the scraper loosens.
For sale by leading Canadian jobbers.
Manufactured by
PILLEY PACKING AND FLUE BRUSH MFG. CO.
623 South Third Street - - - St. Louis, Mo.
Eastern Office: 71 Fulton St., New York.

NATIONAL Boiler Girth Seam Protector

Protection means longer life and greater efficiency

If your Boiler is not Fire-cracked it eventually will be. Prevent this by putting on a National Boiler Protector. You will save cost in repairs and prolong life of the boiler. All new boilers should be protected. If your girth seam is giving you trouble at the present time, have the seam caulked up, attach one of these proteotors and the seam will remain absolutely dry thereafter.



Guaranteed for one year. We make protectors for patches and all styles of boilers. For full particulars, write—

Public Finance Disaster of Early Canadian Days

The almost forgotten experience of our forefathers, of which, to quote Sir Oliver Mowatt, "The effect was to diminish the value of municipal securities generally, and to corrupt the moral sense of the people with reference to moral obligations," makes a fascinating and thought-stimulating article as presented by Dr. J. Murray Clark in recent issues of THE FINANCIAL POST.

Dr. Clark, dealing with this Municipal Loan Fund of the fifties, says of its author, Sir Francis Hincks:

> He had in some respects genuine ability and, in matters which he understood, rendered considerable useful public service, but he was an idealist and a theorist without any practical grasp of the rigorous laws and unyielding facts of finance. He was patriotic and well-meaning, but his patriotism and good intentions did not save the country from the inevitable consequences of his scheme which those able to think clearly on matters of finance perceived from the beginning. He possessed in an eminent degree that fatal fluency of persuasive speech with which so many of our politicians are endowed, and swayed the people, for whom he expressed and probably felt sincere devotion, with superficial catchwords and glittering generalities not founded on the stern realities of economic laws. The confidence he inspired only enabled him to do infinitely more mischief than would otherwise have been caused by his scheme, and did not protect the people from the losses and distress resulting from disregard of sound business principles.

There is more here than an interesting story of early days. Here is a marking on the map of Canada's history by which all interested in the country should make their reckonings, should chart their course of action.

THE FINANCIAL POST is continually presenting such articles. Consider some which appeared in the early issues of August:

Grain Growers Condemned by a Retailer.
Bolshevism and Public Morals.
Some Alberta Oil Wells Are Showing Profit.
Bright Outlook for Canadian Pulp & Paper.
Why Henders Fell Out With Grain Growers.
Sawyer-Massey on the Road to Better Times.
Sir Adam Gets in Some Fine Work at Guelph.
Dominion Loan Campaign to Start Oct. 27.
Frank A. Vanderlip Continues His Vivid Survey of War-ridden Europe.
Make Maturities of Loans as Short as Possible.
Tariff Action by Liberals Step in Dark.
Canners' Head Gives Answer to Prof. Jackson.
Small Retailer Renders Service to the Community.
Reorganization of the Standard Reliance Corporation.
British Will Not Unload Their Canadian Bonds

You will find enlightenment in the balanced viewpoint of THE FINANCIAL POST'S articles and editorials. You will find its "Answers to Enquiry" department of value. THE POST is the paper for the thinker—be he rich or poor; the paper for the man who is eager to study not only what is best for his business, but what is best for Canada. This is the paper which you may receive weekly for one year at a cost of $3.00. Fill in the attached coupon:

The Canadian Who Bullied the Bolsheviks!

WHEN war broke out, Colonel "Klondyke" Boyle took across, at his own expense, 200 staunch Yukon volunteers. He was sent to Southern Russia, and in six weeks turned the transport system there from chaos into efficiency. He fed the starving Russian and Roumanian armies. He arranged temporary peace terms between Bolsheviks and Roumanians. Aided by twenty Chinese murderers and a brave Canadian girl, he bluffed the Bolsheviks and Austrians, in a tremendous exploit which won for him the title "Saviour of Roumania," and the personal thanks of the Roumanian royal family.

Read this story of "Klondyke" Boyle, by Arthur Beverley Baxter, in September MACLEAN'S—it starts on page 13.

"Growing Under Gouin"

—tells the amazing story of development of Quebec Province during the past fourteen years —in road-building, finances, industries and education.

"Meet Mr. Habitant"

—What does the rest of Canada know about the Habitant of to-day? Does he talk like Drummond's poems? This article, by Thomas M. Fraser, forcibly depicts the assets Canada has in French-Canadian stability and thrift, and will go far to remove any lingering prejudices which may exist in some minds.

Other Big Features

The Crowning of the King—By J. K. Munro, the pungent, pithy, political pundit.

Nuorteva's Propaganda—By C. H. Cahan, K.C., recently Director of Public Safety.

The White Eagle at Niagara—By Major C. R. Young, late adjutant Polish Army Camp.

The Problem of Our New Canadians—By Nellie McClung.

His Majesty's Well-Beloved—By Baroness Orczy.

Canada's Great National Asset—By D. B. Hanna, president Canadian National Railways.

Teddy Bear—A wonderful, poignant, Robert W. Service poem.

On Leave—A light, frolicsome story by Harry Bailey.

Evil Spirits—Another Bulldog Carney story, by W. A. Fraser.

Ebb and Flow—A new story by C. W. Stephens, who wrote "Man and Wife."

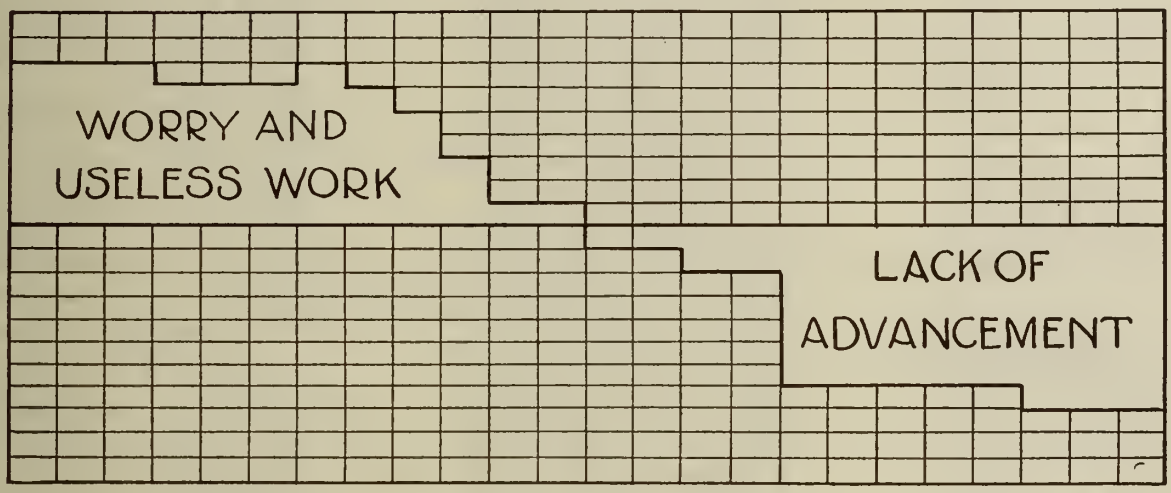
Let the C.A.S.E. Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

Johns-Pratt Co., The, Hartford, Conn.

PACKING, ALL KINDS
Garlock Packing Co., Hamilton, Ont.
Williams Machinery Co., A. R., Toronto.

PACKING ENGINE
Shell Bar Boico Supply, Ltd., Toronto.
Garlock Packing Co., Hamilton, Ont.
Johns-Pratt Co., The, Hartford, Conn.
Shell-Bar, Boico Supply, Ltd., Toronto, Ont.

PACKING FIBRE
Beveridge Paper Co., Ltd., Montreal, Que.
Johns-Pratt Co., The, Hartford, Conn.

PACKING, HYDRAULIC
Shell Bar Boico Supply, Ltd., Toronto.
Can. H. W. Johns-Manville Co., Toronto, Ont.
Durahla Manufacturing Co., New York.
Garlock Packing Co., Hamilton, Ont.
Shell-Bar, Boico Supply, Ltd., Toronto, Ont.

PACKING, METALLIC
Can. H. W. Johns-Manville Co., Toronto, Ont
Shell Bar Boico Supply, Ltd., Toronto.
Garlock Packing Co., Hamilton, Ont.
Greene, Tweed & Co., New York.
Holmes Metallic Packing Co., Wilkesbarre, Pa
Steel Mill Packing Co., Windsor, Ont.

PACKING, ROD
Shell Bar Boico Supply, Ltd., Toronto.
Can. H. W. Johns-Manville Co., Toronto, Ont
Garlock Packing Co., Hamilton, Ont.
Steel Mill Packing Co., Windsor, Ont.
Shell-Bar, Boico Supply, Ltd., Toronto, Ont.

PACKING, SHEET
Can. H. W. Johns-Manville Co., Toronto, Ont.
Shell Bar Boico Supply, Ltd., Toronto.
Durahla Manufacturing Co., New York.
Garlock Packing Co., Hamilton, Ont.
Jenkins Bros., Ltd., Montreal.
Johns-Pratt Co., The, Hartford, Conn.

PACKING, AMMONIA, STEAM AND WATER
Can. H. W. Johns-Manville Co., Toronto, Ont
Garlock Packing Co., Hamilton, Ont.
Greene, Tweed & Co., New York.
Johns-Pratt Co., The, Hartford, Conn.
Steel Mill Packing Co., Windsor, Ont.

PACKING, LEATHER
Garlock Packing Co., Hamilton, Ont.
Graton & Knight Mfg. Co., Montreal.
Shell-Bar, Boico Supply, Ltd., Toronto, Ont.

PACKING PISTON
Garlock Packing Co., Hamilton, Ont.
Shell Bar Boico Supply, Ltd., Toronto.

PACKING, VALVE STEM
Garlock Packing Co., Hamilton, Ont.
Shell Bar Boico Supply, Ltd., Toronto.
Johns-Pratt Co., The, Hartford, Conn.

PAINT OIL STORAGE AND HANDLING SYSTEMS
S. F. Bowser Company, Limited, Toronto, Ont.

PAINTS
Shell Bar Boico Supply, Ltd., Toronto.

PAPER, INSULATING, ETC.
Beveridge Paper Co., Montreal, Que.

PENSTOCKS
Boving Hydraulic & Eng. Co., Ltd., Lindsay, Ont
MacKinnon Steel Co., Sherbrooke, Que.
Wm. B. Scaife & Sons Co., Pittsburg, Pa.

PILLOW BLOCKS
Goldie & McCulloch Co., Galt.
Waterous Engine Works Co., Brantford.

PIPE COILS
Frick Co., Waynesboro, Pa.
York Mfg. Co., York, Pa.

PIPE COVERINGS, STEAM, BRINE, AMMONIA AND ICE WATER
Armstrong Cork & Insulation Co., Montreal, Que.

PIPE STEEL
Boving Hydraulic & Eng. Co., Ltd., Lindsay, Ont

PIPE VISES AND CUTTERS
Armstrong Mfg. Co., Bridgeport, Conn.

PIPE, GAS
Can. Allis-Chalmers, Ltd., Toronto, Ont.

PIPES, WATER
Boving Hydraulic & Eng. Co., Ltd., Lindsay, Ont.
Wilson Mfg. Co., J. C., Belleville.

PIPING AND FITTINGS
Frick Co., Waynesboro, Franklin Co., Pa.
Lunkenheimer Co., Cincinnati, O.
McAvity & Sons, T., St. John, N.B.
Jas. Morrison Brass Mfg. Co., Toronto.
York Mfg. Co., York, Pa.
Williams Machinery Co., A. R., Toronto.

PIPING, STEAM
Babcock & Wilcox, Ltd., Montreal.
Goldie & McCulloch Co., Galt.

PLATE WORK
Goldie & McCulloch Co., Galt.
Engineering and Machine Works of Canada, Ltd.
Mackinnon Steel Co., Ltd., Sherbrooke, Que.
St. Catharines, Ont.
Waterous Engine Works Co., Brantford.

PLUG COCKS
Homestead Valve Mfg. Co., Pittsburgh, Pa.

PLUMBING SUPPLIES
Empire Mfg. Co., Ltd., London, Ont.
Mueller Mfg. Co., H., Sarnia, Ont.
Jas. Morrison Brass Mfg. Co., Toronto.

POWER HOUSE CONVEYORS
Can. Link-Belt Co., Toronto, Ont.

POWER PUMPS (OIL, GASOLINE)
S. F. Bowser Company, Limited, Toronto, Ont.

POWER PUMPS
American Steam Pump Co., Battle Creek, Mich
Boving Hydraulic & Eng. Co., Ltd., Lindsay, Ont
Canadian Fairbanks-Morse Co., Ltd., Montreal.
Darling Bros., Montreal.

WANTED

A firm of Canadian engineers to manufacture and sell on royalty basis a hand operated stoker. This is an established appliance, and is the ideal installation for the small plant, where investment cost is an important item. Combustion principles are same as on highest priced automatic stokers. The ideal stoker for the Canadian market, where the one boiler plant is in the majority.

BOILER INSPECTION

The Steam Boiler Act, Chapter 252 R.S.O., 1914 With Amendments Chapter 58—6, George V.

STEAM BOILERS.

All Steam boilers constructed for use in Ontario must be built from designs which have been approved and allotted a registration number by the Steam Boiler Branch.

Used boilers, boilers sold or exchanged, and unregistered boilers brought into the Province must be inspected prior to being put into operation.

Notice of repairs to steam boilers, stating the nature and extent of same, must be sent to the Steam Boiler Branch, and should such repairs be considered extensive by the Chief Boiler Inspector, the boilers will require to be inspected.

In each and every case the inspections must be made by Inspectors authorized to inspect boilers under the Steam Boilers Act, who are employed only by the Steam Boiler Branch of the Department of Public Works. Official certificates with the maximum working pressure stated thereon are issued to the owners of the boilers so inspected.

STEAM PIPING.

Drawings and Specifications of all high pressure steam piping must be approved and registered by the Steam Boiler Branch before any work of installation is commenced. The drawings submitted should show clearly the dimensions and layout of the main steam lines. Full particulars should be given as to the material used in the construction of the piping, and all valves and other fittings used in connection therewith must be of approved make.

Any deviation from the above requirements shall be deemed a violation of the Steam Boilers Act.

All communications in this respect should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

HON. F. G MACDIARMID, Minister of Public Works and Highways

W. A. RIDDELL, M.A. Ph.D., Supt. Trades & Labour Branch

D. M. MEDCALF,
Chief Inspector of Steam Boilers.

The Quality Standard That Produces "Plus Service" Belting

The only sure way to get satisfactory service is to buy products of known worth.

In Dominion Rubber System Belting, the worth is known because every ounce of material—each individual operation and each finished belt must test up to the highest quality standard ever made for belting.

From the time the materials come into our factory until the belt is running on your pulleys, there is no chance of your getting anything but "plus service" belting.

This is the result of over fifty years of belt making experience and research by the oldest, largest and most completely equipped rubber organization in Canada.

The rubber that goes into Dominion Friction Surfacing Belting is not a mere waterproofing substance—our chemists have given it a far greater value by making it into a friction compound that prevents practically all power wastage on the pulleys.

"Plus service" includes the free technical advice of our belting engineers who are ready to help you with your transmission and conveying problems without placing you under obligation to us.

A phone call, wire or letter to our nearest branch places all of our facilities at your disposal.

CASTINGS IRON and BRASS

These cast iron pipes ranging in size up to 24 in. in diameter and 14 ft. long, are representative of a large order of piping and fittings recently supplied the Brantford Water Commissioners.

The recent additions to our foundry have put us in a better position than ever before to supply your casting wants.

We supply grey iron castings up to 20 tons, also Brass, Bronze and Aluminum castings, either rough or finished.

You can be sure of their strength, smoothness and uniformity of texture, as we analyze all materials to insure a perfect product. The work is turned out true to pattern and readily machined.

THEY ARE NOT GOING TO BE DENIED THE SHOWER NOW

A 932—Nickel plated Shower with rain shower head, rubber tubing faucet connection and round curtain ring, with white duck curtain and wall hook.

THEY met it first in the training camps —it was part of their treatment in the convalescent hospital—it was included in the routine of the demobilization camps.

So the best of Canada's young men have become educated to the Shower—they know what it means to their health.

It is up to you to see that they get a Shower in their homes—the kind of shower that will give satisfaction—an EMPIRE SHOWER.

Let them know that you can supply the Portable Shower illustrated here.

It is specially adapted for use when a permanent shower is not practicable in a rented house, an apartment, or other places where space is limited. It is all that a shower should be.

Empire Permanent Showers in the latest and improved designs will be in demand as well.

You are going to be called on for Shower estimates.

Write for our catalogue and order direct from us.

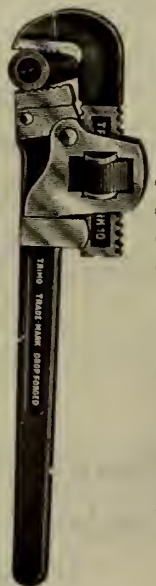
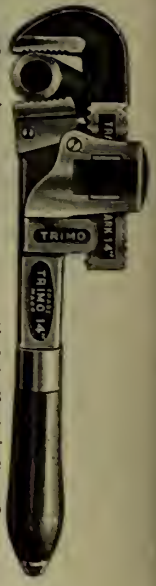
TRIMO
THE WORD TRIMO



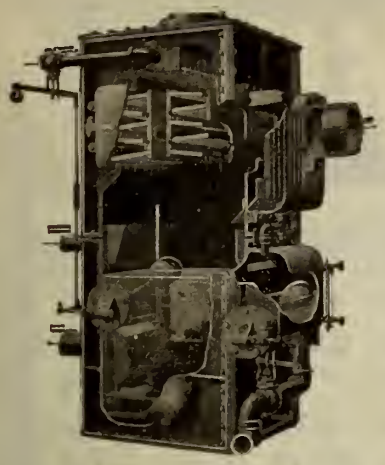
Stands for good tools made by the Trimont Mfg. Co., which are the following:—

The Trimo Pipe Wrench
The Trimo Chain Pipe-Wrench
The Trimo Monkey Wrench
The Trimo Pipe Cutter (Hand)



The four good points that make **Trimo** Pipe Wrenches superior are the Spiral Spring always in place—Steel Frames that will not break—Nut Guards that protect adjustment nut—and the Inserted Jaw in handle that can be replaced when worn —Save Money and buy Trimo goods, made by

Trimont Mfg. Company
Roxbury (Boston), Mass.



5,000 series Cochrane Open Heater for back pressure service, used in connection with heating systems

SAVE A PILE OF COAL

BY using exhaust steam you may reduce your fuel consumption ten to fifty per cent. Where exhaust steam is used in heating, drying, etc., the cost of power is practically nothing, as it becomes a by-product. If you have more exhaust steam than you can utilize for heating, drying and similar purposes, turn it into the intermediate stage of the main turbine or into a low-pressure turbine. To prevent the vacuum from the turbine backing up into the engine exhaust line, and drawing in air, to the detriment of the condenser vacuum, install a Cochrane Multiport Flow Valve in the engine exhaust connection.

Use exhaust steam for heating water for boiler feeding, washing,dyeing, scouring, paper making, hot water heating, etc. In the Cochrane Open Heater the water comes into actual, immediate contact with exhaust steam and is heated to the full steam temperature. There is no loss of temperature due to transmission through metal plates or to accumulations of grease or scale upon heating surfaces. The exhaust steam condensed in heating the water is added thereto, so that one pound of exhaust steam and six pounds of cold water produce seven pounds of water at 210 degrees F., or hotter, depending upon the back pressure carried.

Heating the boiler feed from hot well temperature, say 90 degrees F. to 210 degrees F., will reduce the amount of fuel required under the boilers by at least ten per cent. If your feed water is colder than 90 degrees F., larger savings are possible.

If large quantities of hot water are used intermittently, as in textile mills, paper mills, laundries, etc., a Cochrane Heater of the extra storage type can be used both for heating and storage.

Fig. 1000 — Multiport Back Pressure Relief Valve "Note Multiple Disks"

For regulating the pressure upon the exhaust steam system, use the Cochrane Multiport Safety Exhaust Outlet Valve. In this valve, noise, clatter and injury to valve and seats are avoided by the use of a number of small disks instead of one large disk. Each disk is provided with an independent dash pot and held to seat by an independent spring, the tension of all the springs being adjusted simultaneously by a pressure plate. The motion of this plate is limited, so that a predetermined back pressure cannot be exceeded. The adjustment of the back pressure is controlled by a hand-wheel on the outside of the casing, or from a distance by means of chains, rods or levers. The pressure can be changed quickly with little effort.

Ask for Bulletins 710 on Heaters, 601 on Multiport Valves

GARLOCK PACKINGS

BETWEEN THE COAL PILE AND THE ENGINE

At this time more than any time in the history of engineering, highest efficiency is demanded. A blown out gasket can shut down a plant just as surely as a broken piston rod. Every leaking manhole joint or pipe flange represents a distinct loss, and it has been demonstrated by scientific experiment that there is no limit to the loss caused by undue friction on piston rod and valve stem packed with an inferior packing, and the constant use of a wrench in attempting to stop leaks at rod glands. Let Garlock No. 950 Gasket, cut from No. 900 Sheet Packing, reduce the loss between coal pile and engine.

THE GARLOCK PACKING CO.
HAMILTON, ONT.

SPARE THE ROD

Is the ash barrow the hearse for your boiler settings?

SLICING of brickwork away from setting walls along with the clinker is expensive but readily understood when you stop to think that—under the high temperature of the fire box—the clinker welds to and frequently penetrates into the pores of the fire brick.

By coating the flame-exposed brickwork with Johns-Manville No. 32 High Temperature Cement, a surface is obtained that does not allow the clinkers to anchor themselves into the fire brick and enables them to be removed without tearing the brick surface away.

Joints between fire bricks in boiler settings, when laid up in No. 26 or No. 31 High Temperature Cements, absorb expansion and contraction stresses, and prevent spawling, cracking and air leaks. Furnaces so treated require minimum attention and give maximum service. Read about Johns-Manville Heat Treatment in the booklet that any branch will send at your request.

Every Part of Every FRICK INSTALLATION Must Be Perfect in order to maintain

FRICK SUPERIORITY

That is why Frick Refrigerating and Ice Making Equipment proves a profitable investment wherever installed.

The entire Frick line, from the smallest to the largest plant, from the smallest part to the largest part in each plant, is designed to meet our strict standard of Durability—Efficiency—Economy. Every part must be perfect in order to maintain the well-known FRICK Superiority.

Therefore, when you purchase FRICK Equipment you are assured of perfect service regardless of the unforeseen overload demand that might be placed on it sometime—assured of continued operation without danger of breakdowns in the midst of a busy season—assured of economical operation at all times—and a long life. Frick Equipment has been standing up under the above conditions for nearly a half-century, day after day, year after year, under the most severe conditions.

You can't go wrong when you specify "Frick Equipment." **Catalog on request.**

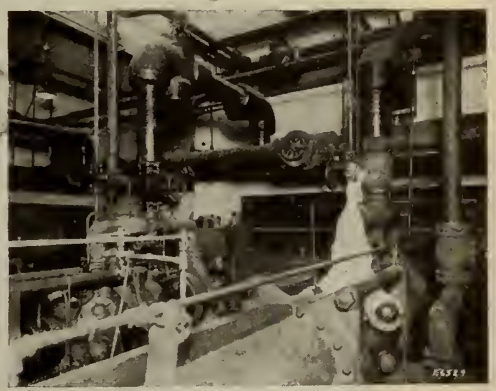
A Covering for Cold Pipes That Will Last

IF you consider durability a factor of importance when buying insulation for cold pipes, here is a rule that it will be well to follow: *Be sure that the covering you buy will not absorb moisture.* For moisture, always present in the atmosphere, is the greatest enemy of cold pipe insulation. Because of the peculiar nature of cork,



Nonpareil Cork Covering on the ammonia lines in the plant of the Chicago Cold Storage Company, Chicago, Ill.

Nonpareil Cork Covering

For All Cold Pipes

has the necessary qualities that enable it to stand up under hard service conditions. In the first place, cork is cellular in structure—not fibrous—and does not suck in moisture from the air by capillary attraction. In the second place, it is coated inside and out with a waterproof mineral rubber finish, and when applied, all joints are sealed with waterproof cement. Given a reasonable amount of attention, Nonpareil Cork Covering will last for years, and will pay for itself many times over in refrigeration saved.

Before you contract for cold pipe covering, read the 64-page illustrated book, "Nonpareil Cork Covering for Cold Pipes." A copy will be sent you, free of charge, on request.

Armstrong Cork & Insulation Company, 504 McGill Building, Montreal, Quebec, Canada

Also manufacturers of Nonpareil Corkboard Insulation for cold storage rooms; Nonpareil High Pressure Covering for steam lines; Nonpareil Insulating Brick for boiler settings; Nonpareil Cork Machinery Isolation for deadening the noise of machines; and Circle A Cork Brick for cold storage room floors.

York Refrigerating Machinery

QUALITY—SERVICE

From the very beginning we have been building **quality** and **service** into our Refrigerating Machines. This has resulted in increasing sales of our products and increasing satisfaction on the part of our customers.

With a York Refrigerating Plant you can improve the quality of **your** product as well as the measure of service **you** render to your trade.

Any firm that installs a Refrigerating Plant is looked upon by the trade it serves as a progressive firm. Give MECHANICAL REFRIGERATION a chance. In these days of keen competition it is the progressive owner who survives and profits.

In the LARGEST and MOST MODERN PLANT in the WORLD, building Insulated DOORS and allied products exclusively, we are building what we KNOW to be THE BEST INVESTMENT FOR THE USER and the universally recognized WORLD'S STANDARD DOORS. In verification:—

THE HARRIS ABATTOIR CO., Ltd., Canada.

"Our Coolers and Freezers are mostly equipped with your doors. In fact we adopted it as *Standard throughout our plant*, as we find *them substantially made* and the *insulation perfect*. We also find the *Hardware stands up better than on any other door* we have seen or tried."

LOUISVILLE SOAP CO., Louisville, Ky.

"Coolers at one of our plants are *equipped with your doors, which have given us such satisfaction we wish to improve the doors at our old plant*. We would not be warranted in throwing out the doors but would like the type hardware you supply."

THE WASHINGTON MARKET, Washington, D.C.

"The *doors supplied by you*, in use at both plants, *have been in every way satisfactory*, and we think the *Jamison door is the best on the market*."

Read 'em again, men—analyze them! Acquaint yourself fully with our method of construction through latest catalog No. 8.

In Canada's Biggest Industries

Where absolute certainty must be counted upon at all times, no chance can be taken with equipment.

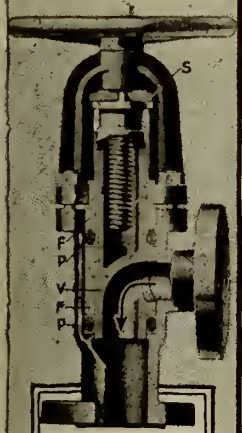
In the big industries, especially must every detail be efficient—the blow-off valve as well as the boilers, pumps and engines.

So, when the big Canadian corporations such as the following instal Yarway (formerly the Simplex) "Seatless" Blow-Off Valves, their choice becomes an endorsement of the very highest character.

Canadian Explosives Co., Ltd., have 11.
Dominion Iron & Steel Co., Ltd., have 20.
Canadian Pacific Railway Co., have 24.
Bathurst Lbr. Co. have 8.
Montreal L., H. & P. Co. have 24.
International Eng. Wks., Ltd., have 13.

And there are many others. With the Yarway (formerly the Simplex) "Seatless" Blow-Off Valve there can be no sudden opening and closing to injure tubes; the operation is simple, certain and safe; the valve does not leak; it requires but little attention, as there are no weak places such as seats or discs to cut and scar; even the packing lasts for years. You can verify each of these claims by testing the Yarway on one of your boilers for 60 days. Return it if not satisfactory.

Write to-day, stating size of line, and whether screwed or flanged, angle or straightway.



Operation: In closing valve shoulder "S" on plunger "V" engages the lose follower gland "F," compressing packing "P" above and below the port, making an absolutely tight valve.

Something New for Stoker Users

You have often needed a Fuel Control Device that would build up that thin spot—or burn down that heavy spot without poking, levelling or slicing.

The RILEY 2-SPEED GEAR BOX is the control you have long wished for. It is almost a magic tool—it is like being able to drop a shovelful of coal here or there without opening the fire door or disturbing the conditions of the furnace.

A single throw of the shifter lever operates the 2-speed Gear Box. There is nothing to get out of order—nothing that is complicated—nothing that is hard to understand. Even the inexperienced can manipulate the fires or balance the load among any number of stokers with mechanical certainty that will save your coal, utilizing the last B.T.U. in the fuel.

Riley Underfeed Stokers

equipped with the 2-SPEED GEAR BOX with either engine or motor drive give the ideal equipment for Central Station or Industrial Service.

If you want to pick up your load from banked fire to 200 or 300% of rating almost instantly or drop it just as quickly without wasting coal—then you need the RILEY 2-SPEED GEAR BOX. Publication No. 40 tells you how it does it.

For information on Murphy Automatic Furnaces for smaller boilers, see advertisement in last issue or send for Murphy Catalog H-M 10.

We Trained Last Year 1000 Men for U.S. Government

Up-to-Date Stationary Engineers are in Demand

This modern course of study covers every branch of power-plant work, including Steam Engineering, Practical Mathematics and Electric Wiring—all the principles of practical electricity. The Course has been prepared by a staff of experts working under the personal supervision of Joseph G. Branch, B.S., M.E., author of many standard books and for many years Chief Engineer of the City of St. Louis and a member of the Examining Board of Engineers for that city. Although complete in every detail, the Course is written so simply and clearly that anyone can understand it. No useless theory—but all the straight **facts** you need to pass the Engineer's Examinations and hold down a good job. You can substitute **Mechanical Refrigeration** for **Electrical Wiring** at the same price for the course.

All Text Books Furnished FREE

Five text books, handsomely bound, printed in large, clear type on fine quality paper, are furnished absolutely FREE with this course. They are sent to you at once. You do not have to wait several weeks or months, you get all the books **immediately.** Besides the books you get all necessary stationery and envelopes for answering questions and making recitations. There are no extras of any kind.

Graded Certificates for Ontario Engineers

The Following Set of Regulations Make Provision for Carrying Out of the Act by Which Certificates Will Be Graded in Ontario, Beginning January, 1920—These Regulations Are Worthy of the Closest Study by Operating Engineers and Firemen.

Regulations Set By Order-in-Council Respecting Stationary Engineers

NO person who is not the holder of a certificate of qualification issued by the Minister of Public Works of Ontario, shall operate in this Province any stationary steam boiler or engine of fifty B.H.P. or over, or any steam heating plant operating at a pressure of over twenty pounds. Every person who operates a steam plant as the engineer in charge thereof, contrary to the above regulation, and every person employing him or permitting him so to do is subject on summary conviction to a penalty of not less than ten dollars.

This provision shall not apply to firemen who are taking their required six months' training under a certificated engineer, but it shall apply to all firemen who have had six months' experience, and to all night watchmen who are employed at plants of 50 B.H.P. or over, carrying over 20 pounds steam. At the expiration of this six months' initial training all firemen must make application of a Fourth-class Certificate. Anyone omitting to comply with this regulation shall be subject to the penalty set forth in Section 15 of the Act.

Any engineer who fails to keep his certificate exposed to view at all times in the engine or boiler room in which he is employed, shall be liable to a fine of ten dollars.

Certificates by Examination

Certificates are of four grades, viz.:—
First Class,
Second Class,
Third Class and
Fourth Class.

Fourth-class Certificates

Any person who desires to operate under a certificated engineer, a stationary steam plant of 50 B.H.P. or over, which carries over 20 pounds steam, must hold a Fourth-class Certificate. (Application forms for this certificate will be supplied on request).

A candidate for a Fourth-class Certificate shall be required:—

(a) To be at least 19 years of age;
(b) To furnish sufficient proof that he has had the required six months' initial experience;
(c) To satisfy the Board as to character and sobriety;
(d) To answer orally the questions on the examination paper, and secure at least sixty per cent. of the marks;
(e) To pay a fee of five dollars at the time application is made for examination. (This fee shall not be returned to the applicant should he fail to pass the examination).

Examinations shall consist of questions upon the construction of steam boilers and steam pumps, and upon hydraulics.

In the event of a candidate failing in his examination, ninety days shall elapse before he becomes eligible for re-examination.

Candidates shall be examined in Toronto during the first week of each month by appointment at the office of the Board of Stationary and Hoisting Engineers, Parliament Buildings, or at such other places as may be designated by the Board; and the Board may also conduct examinations twice in each year on such dates as may be determined:—

(a) In the City of London;
(b) In the City of Kingston;
(c) In the City of Ottawa;
(d) In the City of Port Arthur;

and at such other times and places as may be considered desirable by the Board.

Notice of the time and place of holding the examinations shall be sent to each candidate living in the district where the examination is held.

Third-class Certificate

Any person who desires to take charge of a stationary steam plant of between 50 and 150 B.H.P. must hold a Third-class Certificate. (Application forms for this certificate shall be supplied on request).

A candidate for a Third-class Certificate shall be required:—

(a) To be at least 21 years of age;
(b) To be the holder of a Fourth-class Ontario Certificate or its equivalent from one of the other Provinces of the Dominion;
(c) To furnish evidence to the effect that he has had at least two years' experience as fireman, oiler, or assistant to the engineer;
(d) To answer the questions on the examination paper and secure at least sixty per cent. of the marks;
(e) To pay a fee of five dollars at the time of making application for examination. (This fee shall not be returned to the applicant should he fail to pass the examination).

Examinations shall consist of questions upon the construction and operation of steam engines, steam boilers, and steam pumps, and upon hydraulics.

Examination questions shall be furnished only at the time of examination, and under no circumstances shall they be furnished by mail.

Examinations shall be written but should the Board

deem it necessary it may subject the applicant to an oral examination on the questions contained in the examination paper and may have him demonstrate his knowledge of the operation of a steam plant in an engine or a boiler room.

In the event of an applicant failing in his examination, ninety days shall elapse before he becomes eligible for re-examination.

Candidates shall be examined in Toronto during the first week of each month by appointment at the office of the Board of Stationary and Hoisting Engineers, Parliament Buildings, or at such other place as may be designated by the Board. Also, examinations may be conducted by the Board twice in each year on such dates as may be determined:—

(a) In the City of London;
(b) In the City of Kingston;
(c) In the City of Ottawa;
(d) In the City of Port Arthur;

and at such other times and places as may be considered desirable by the Board.

Notice of the time and place of holding the examination shall be sent to each candidate living in the district where the examination is held.

Second-class Certificates

Any person who desires to take charge of a stationary steam plant between 150 and 300 B.H.P. must hold a Second-class Certificate. (Application forms for this certificate shall be supplied on request).

A candidate for a Second-class Certificate shall be required:—

(a) To be the holder of a Third-class Certificate or its equivalent from one or the other Provinces of the Dominion;

(b) To furnish evidence to the effect that he has had at least five years' experience;

(c) To answer the questions on the examination paper, and secure at least sixty per cent. of the marks).

(d) To pay a fee of five dollars at the time of application is made for examination. (This fee shall not be returned to the applicant should he fail to pass the examination).

Examinations shall consist of questions upon the construction and operation of steam engines, steam boilers and steam pumps, and upon hydraulics, refrigeration, and the care of electric motors and generators.

Examination questions shall be furnished only at the time of examination, and under no circumstances shall they be furnished by mail.

Examinations shall be written, but should the Board deem it necessary it may subject the applicant to an oral examination on the questions contained in the examination paper, and may have him demonstrate his knowledge of a steam plant in an engine or a boiler room.

In the event of an applicant failing in his examination, ninety days shall elapse before he becomes eligible for re-examination.

Candidates shall be examined in Toronto during the first week of each month by appointment at the office of the Board of Stationary and Hoisting Engineers, Parliament Buildings, or at such other place as may be designated by the Board. Also, examinations may be conducted by the Board twice in each year on such dates as may be determined:—

(a) In the City of London;
(b) In the City of Kingston;
(c) In the City of Ottawa;
(d) In the City of Port Arthur;

and at such other times and places as may be considered desirable by the Board.

Notice of the time and place of holding the examination shall be sent to each candidate living in the district where the examination is held.

First-Class Certificates

Any person who desires to take charge of a stationary steam plant of unlimited capacity must hold a First-class Certificate. (Application forms for this certificate shall be supplied on request.)

A candidate for a First-class Certificate shall be required:—

(a) To be the holder of a Second-class Certificate or its equivalent from one of the other Provinces of the Dominion;

(b) To furnish evidence to the effect that he has had at least ten years' experience, showing seven years as chief or operating engineer;

(c) To answer the questions on the examination paper and secure at least seventy per cent. of the marks;

(d) To pay a fee of ten dollars at the time application is made for examination. (This fee shall not be returned to the applicant should he fail to pass the examination.)

Examinations consist of questions upon the construction and operation of steam engines, steam boilers and steam pumps, and upon hydraulics, refrigerating, generators, steam heating and ventilating, and the care of electric motors, together with questions on the general management of the plant.

Examination questions shall be furnished only at the time of examination, and under no circumstances shall they be furnished by mail.

Examinations shall be written, but should the Board deem it necessary it may subject the applicant to an oral examination on the questions contained in the examination paper, and may have him demonstrate his knowledge of a steam plant in an engine or a boiler room.

In the event of an applicant failing in his examination, ninety days shall elapse before he becomes eligible for re-examination.

Candidates shall be examined in Toronto during the first week of each month by appointment at the office of the Board of Stationary and Hoisting Engineers, Parliament Buildings, or at such other place as may be designated by the Board. Also, examinations may be conducted by the Board twice in each year on such dates as may be determined:—

(a) In the City of London;
(b) In the City of Kingston;
(c) In the City of Ottawa;
(d) In the City of Port Arthur;

and at such other times and places as may be considered desirable by the Board.

Notice of the time and place of holding the examination shall be sent to each candidate living in the district where the examination is held.

As to Certificates

A certificate of any grade shall be good only until the 31st day of December of the year for which it is issued, and shall lapse at that time. Any engineer who fails to renew his certificate shall not be allowed to continue in charge of a steam plant.

Every certificate holder who intends to renew his certificate shall register with the Board not later than the FIRST DAY OF DECEMBER of each year, on a form which will be supplied. A certificate holder who has not registered by the FIRST DAY OF FEBRUARY next en-

suing shall be granted a renewal only on the payment of a fee of five dollars.

On receipt of his certificate the engineer to whom it is granted shall sign the same in ink in the space provided for that purpose on the margin of the certificate, and shall at all times keep his certificate exposed to view in the engine or boiler room where he is employed.

Any person who was the holder of a Stationary Engineer's Certificate issued by the Board of Stationary and Hoisting Engineers of Ontario, before the enforcement of this Act (January 1st, 1920), shall be allowed to continue in his present position, but should he make any change in his position he must inform the Board of all particulars of the plant which he desires to operate, as to B.H.P., size of boiler or boilers, steam pressure, etc., and qualify for and obtain the certificate which applies to said plant, provided he is not already the holder of such a certificate.

As to Grading Certificates

Application forms shall be forwarded to every engineer who held a Stationary Engineer's Certificate for the current year previous to January 21st, 1920. Upon receipt of same the Board shall pass upon and grade the applicants accordingly into Third or Second-class. A First-class Certificate shall be granted by examination only.

As to Night Watchmen

Anyone desiring to act in the capacity of night watchman must hold at least a Fourth-class Certificate from this Board.

As to Returned Soldiers

Any returned soldier, who has completed a vocational course in Stationary Engineering at any recognized school in the Dominion of Canada shall, upon submitting sufficient proof to this effect, be granted the privilege of writing on the examination for a Third-class Certificate.

As to the Absence of the Chief Engineer

In the temporary absence of a Chief Engineer, an engineer holding a certificate of one grade lower may take charge and operate in his stead for a period not to exceed thirty days.

An extension of this period may be granted under special circumstances upon application to the Board.

Where a plant is operated in two or more shifts under a Chief Engineer, said Chief shall arrange that an engineer holding a certificate of the same grade as his own, or one grade lower, take charge of same in his absence; and when a plant is operated in two or more shifts and no Chief Engineer is employed, each shift shall be in charge of an engineer holding a certificate of the grade required by the Act.

Partial Operation of Plants at Night

In a case where a plant is partially operated at night, said plant may be operated by an engineer holding a certificate of one grade lower than would be required by the Act if the same was in full operation.

Ao to Provisional Certificates

Any engineer, who is the holder of a certificate of qualification from any other Province of the Dominion of Canada, and who furnishes satisfactory evidence as to character and sobriety, together with the prescribed fee of five dollars, shall, upon presenting his certificates to the Board for verification, be granted a Provisional Certificate of a corresponding grade, to take charge of a stationary steam plant in the Province of Ontario for one year only from date of issue. It will then be necessary for the application to try the prescribed examination in order to obtain a certificate entitling him to take charge of a steam plant coming within the provisions of the Act respecting Stationary and Hoisting Engineers in the Province of Ontario. This regulation does not apply to a First-class Certificate, as no certificate of this grade shall be issued provisionally.

As to Fees

The fee for the Fourth-class Certificate is five dollars.
The fee for the Third-class Certificate is five dollars.
The fee for the Second-class Certificate is five dollars.
The fee for the First-class Certificate is ten dollars.
The fee for re-examination (any grade) is five dollars.
The fee for renewing a Fourth-class Certificate is one dollar.
The fee for renewing a Third-class Certificate is one dollar.
The fee for renewing a Second-class Certificate is one dollar.
The fee for renewing a First-class Certificate is two dollars.
The fee for renewing any certificate, where the holder has failed to register by the first day of February, is five dollars.
The fee for issing a duplicate certificate is one dollar.
The fee for issuing a Provisional Certificate is five dollars.
The fee for re-examination (any grade) is five dollars.
The fee for re-registration of plants is one dollar.

As to Cancellation of Certificates

The Minister of Public Works, on the recommendation of the Board, may, at any time for misconduct or infraction of the provisions of the Stationary and Hoisting Engineer's Act, or of any regulation thereunder, suspend or revoke any certificate, and during such suspension, and until any revocation shall be cancelled by the Minister of Public Works, no further or other certificates to such person shall be issued.

As to Duplicate Certificates

In case a certificate is lost, stolen or destroyed, a duplicate shall be issued on presentation to the Board of a statutory declaration, or other satisfactory proof, setting forth the facts, together with the required fee.

As to Registration of Steam Plants

It shall be the duty of the owner of every plant of fifty B.H.P. or over, which carries over twenty pounds steam, to advise the Board as to the exact dimensions of his steam plant, on a form which shall be supplied upon request.

As to Registration Certificate

A registration form shall be supplied on request to any plant owner or engineer. Upon return of this form with the necessary fee, a Registration Certificate shall be issued by the Board, such certificate to be exposed to view at all times in the boiler or engine room of the plant. Any change made in a steam plant shall necessitate a re-registration.

Failure to comply with this regulation will necessitate the enforcement of sub-section (b), section 15, of the Act repecting Stationary and Hoisting Engineers.

Inspectors of factories are employed to assist in the enforcement of the Act respecting Stationary and Hoisting Engineers.

NOTICE:—It is necessary for a certificate holder to at once notify the Chairman of the Board of any change in his permanent address.

The Stationary Engineer's Certificates issued by the Board of Stationary and Hoisting Engineers are of four grades, viz., Fourth, Third, Second and First-class. Successful candidates are granted certificates, valid for one year dating from January 1st of the year in which they are issued. Certificates are renewable yearly and renewal application forms are sent to all certificate holders by the Board.

How to Obtain Certificates

Those who wish to present themselves for examination for Stationary Engineers' Certificates should apply for an application form to the Chairman of the Board, 15 Queen's Park, Parliament Buildings, Toronto. This should be filled in in detail and returned with the required affidavit and fee.

Candidates desiring theoretical information regarding

the operation of steam plants may obtain same by studying any recognized text-book on the boiler and steam engine.

Candidates will be notified of the date set for the examination and they must appear at the examination room punctually at the time appointed.

No person is allowed in the examination rooms during the examinations, other than those whose duties require them to be present.

Examination questions are furnished only at the time of examination, and under no circumstances can they be furnished by mail.

Any candidate who, because of deficient education, cannot write the answers to the questions himself, may be allowed to secure the service of a person (not an engineer) who will write answers to the questions exactly as instructed by the candidate. In case it is impossible for the candidate to secure the services of such a person, the examiner will write the answers for him or select some one to do so.

Fourth-class Certificates

A candidate for examination for a Fourth-class Certificate must be at least 19 years of age, and must furnish proof of at least six months' experience. He must satisfy the Board as to character and sobriety and pay a fee of five dollars at the time application for examination is made.

The examination for this certificate is oral and based on the candidate's practical knowledge of steam boilers, steam pumps and hydraulics.

The fee is five dollars and should be enclosed when the application form is forwarded to the Board. It will not be returned should the candidate fail to pass the examination.

An affidavit must accompany each application.

Third-class Certificates

A candidate for examination for a Third-class Certificate must be at least 21 years of age, and hold a Fourth-class Ontario Certificate issued by this Board, or its equivalent from one of the other Provinces of the Dominion. He must have had two years' experience as fireman, oiler or assistant to an engineer and must produce testimonials as to such time, the same to be signed by his employer in the case of shop time, and by his employer or the chief engineer in the case of engineer's or fireman's time. These testimonials must state the kind of work the candidate was employed on, and for how long; and give evidence as to his experience, ability, sobriety and general good conduct for at least twelve months preceding the date of application for examination.

The questions on a Third-class examination paper are almost entirely practical in character and may be described as follows:—

(a) Questions relating to the origin of steam and its uses;

(b) Questions relating to the different kinds and manners of constructing boilers to generate steam, including the strength of material used in making boilers;

(c) Questions regarding the different kinds of safety valves for controlling the pressure in steam boilers and other necessary fittings;

(d) Questions regarding the proper methods of raising and maintaining steam in boilers and the care necessary to keep them in good order; and when repairs are necessary, the method of making such repairs;

(e) Questions regarding the kind, construction and operation of the different appliances used to feed and supply boilers with water during operation.

The questions are made as clear and concise as possible, and every effort is made to have them cover such practical knowledge as should be possessed by every engineer charged with the care and operation of steam boilers and engines.

The fee is five dollars and should be enclosed when the application form is forwarded to the Board. It will not be returned should the candidate fail to pass the examination.

An affidavit must accompany each application.

Second-class Certificates

A candidate for examination for a Second-class Certificate must hold a Third-class Ontario Certificate issued by this Board, or its equivalent from one of the other Provinces of the Dominion. He must have had five years' experience acting in the capacity of engineer, assistant engineer, oiler or fireman and must produce testimonials as to such time and employment, the same to be signed by his employer in the case of shop time, and by his employer or chief engineer in the case of engineer's or fireman's time. These testimonials must state the kind of work the candidate was employed on, and for how long; and give evidence as to his experience, ability, sobriety and general good conduct for at least twelve months preceding the date of application for examination.

The questions on a Second-class examination paper are mostly of a practical nature, a few only being based on technical work and may be described as follows:—

(a) Questions relating to the origin of steam and its uses;

(b) Questions relating to the different kinds and manners of constructing boilers to generate steam including the strength of material used in making boilers, and the proper proportion in sizes and thickness of materials to be used, together with proper areas of grate, etc.;

(c) Questions regarding the different kinds of safety valves for controlling the pressure in steam boilers and other necessary fittings;

(d) Questions regarding the proper methods of raising and maintaining steam in boilers and the care necessary to keep them in good order; and when repairs are necessary, the method of making such repairs;

(e) Questions regarding the kind, construction and operation of the different appliances used to feed and supply boilers with water during operation.

(f) Questions regarding the different kinds of boilers and engines used in developing power, including their construction and the methods of calculating their capacity and the proper methods of caring for and operating such boilers and engines.

The questions are made as clear and concise as possible and every effort is made to have them cover such practical and technical knowledge as should be possessed by every engineer charged with the care and operation of steam boilers and engines.

The fee is five dollars and should be enclosed when the application form is forwarded to the Board. It will not be returned should the candidate fail to pass the examination.

An affidavit must accompany each application.

First-class Certificates

A candidate for examination for a First-class Certificate must hold a Second-class Ontario Certificate issued by this Board, or its equivalent from one of the other Provinces of the Dominion. He must have had ten years' experience, during seven years of which he was employed as chief or operating engineer, and must produce testimonials as

to such time and employment, the same to be signed by his employers in the case of shop time, and by his employer or the chief engineer in the case of engineer's or fireman's time. These testimonials must state the kind of work the candidate was employed on and for how long; and give evidence as to his experience, ability, sobriety and general good conduct for at least twelve months preceding the date of application for examination.

The questions on a First-class examination paper are of a practical and highly technical nature and may be described as follows:

(a) Questions relating to the origin of steam and its uses;

(b) Questions relating to the different kinds and manners of constructing boilers to generate steam, including the strength of material used in making boilers, and the proper proportion in sizes and thickness of materials to be used, together with proper areas of grate, etc.;

(c) Questions regarding the different kinds of safety valves for controlling the pressure in steam boilers and other necessary fittings;

(d) Questions regarding the proper methods of raising and maintaining steam in boilers and the care necessary to keep them in good order; and when repairs are necessary, the method of making such repairs;

(e) Questions regarding the kind, construction and operation of the different appliances used to feed and supply boilers with water during operation;

(f) Questions relating to the calculation of safety valve pressure, boiler shells, stays, riveting, feed pumps, indicator diagrams;

(g) Questions relating to the taking off of indicator diagrams, surface and jet condensation, superheating, and the working of steam expansively;

(h) Questions relating to the construction of air-compressors, ammonia-compressors, and dynamos of ordinary types;

The candidate's knowledge of arithmetic must include addition, subtraction, multiplication and division; methods of extracting square and cube root; and the application of arithmetical rules to questions relating to the power, duty, and economy of engines and boilers, and to stresses in rods, shafts, and levers of the engine. He will also be required to make an intelligible hand-sketch or a working drawing of some one or more principal parts of a steam engine, and to mark in, without copy, all necessary dimensions in the figures, so that the sketch or drawing could be worked from. Fine drawing is not expected, and a wide margin will be allowed in the proportions of the parts, but the drawing must be a practical working design, giving a sufficient number of views to show the parts fully, sections, plans, or elevation, just as the candidate would require them to be supplied to him if he had to make the part to the design of another person.

The questions are made as clear and concise as possible and every effort is made to have the questions cover such practical and technical knowledge as should be possessed by every engineer charged with the care and operation of steam boilers and engines.

The fee is ten dollars and should be enclosed when the application form is forwarded to the Board. It will not be returned should the candidate fail to pass the examination.

An affidavit must accompany each application.

How to Obtain Graded Certificates by Application

The Stationary Engineers' Certificates issued by this Board for the year 1919, will be divided for 1920, into two classes, viz., Third and Second-class.

The holders of such certificates, upon making application, will be placed in one of these classes, according to percentage made on examination; length of experience, and testimonials covering same; kind and size of plants they have handled, etc. This application will cover the usual yearly renewal form, the fee being one dollar. Applicants failing to make application for renewal before the 1st of February, 1920, will be granted a renewal only upon the payment of the fee of five dollars; and they will be granted a Third-class Certificate only, irrespective of their qualifications.

Those who were granted Stationary Engineer's Certificates issued by this Board previous to 1919, may renew same upon application and the payment of five dollars. If such application is made previous to February 1st, 1920, they will be graded in the same manner as those who held 1919 certificates.

An affidavit must accompany each application.

How to Obtain a Registration Certificate

The owner of every steam plant of 50 B.H.P. or over, which carries over twenty pounds steam, must hold a Registration Certificate. This certificate is obtained by application, said application form being supplied by the Board, on request. Any change made in a plant will necessitate a re-registration of same, the fee for each registration being one dollar.

An affidavit must acompany each application.

General Information

All correspondence in connection with this Act should be addressed as follows:—

The Chairman,
Stationary and Hoisting Engineers' Board,
Parliament Buildings,
Toronto, Ont.

In the event of any candidate being discovered referring to any book or paper, or copying from another or affording any assistance, or giving any information to another or communicating with another, during the time of examination or copying any part of a question for the purpose of taking the same out of the examination rooms, he will subject himself to the penalties of failure, and will not be allowed to be re-examined for a period of six months.

If the holder of a Stationary Engineer's Certificate for the year 1919 is in charge of a stationary steam plant of 150 B.H.P. or over, he will be entitled under this Act to continue in operation of same under the certificate which will be granted to him from his 1919 certificate, irrespective of the grade issued; but should he change his position he will at once be required to obtain the certificate covering the operation of the plant of which he is desirous of taking charge.

The certificates of any other Province of the Dominion are interchangeable provisionally with those of this Province, with the exception of a First-class Certificate.

THE German mark is so severely discounted now that it pays European firms handsomely to do their purchasing in Germany. In other words, they can make quite a big mark with the little German mark.

CARUSO has an offer to go and sing in Mexico at $10,000 per night. Without going to the extent of disclosing names we know of several folks who will holler themselves hoarse for a whole month for that figure.

Act Grading Certificates for Ontario Engineers

The Act Given Below is Reprinted from April 25 Issue of Power House Owing to the Publication of Regulations Respecting It in This Issue—The Two, Regulations and Act, Should Be Read Together for a Clear Understanding of Each

IN the Act to consolidate and amend the Acts respecting Stationary and Hoisting Engineers, passed April 17, 1919, by the Ontario Legislature, provision was made for the grading of certificates. The Act is given in full below together with explanatory matter. In this Act:—

Act Re Graded Certificates

(a) B.H.P. shall mean boiler horsepower or the equivalent to the evaporation of 34 lbs. of water per hour from and at 212°—15 sq. ft. of heating surface for return tubular boilers—12 sq. ft. heating surface for locomotive type boilers—10 sq. ft. heating surface for water tube boilers;

(b) "Board" shall mean the Board of Examiners appointed as hereinafter provided;

This clause defines what is meant by boiler horsepower in so far as the Act is concerned.
See Section 4.

(c) "Hoisting plant" shall mean and include a steam boiler and steam engine and every part thereof, working at a pressure of twenty pounds or over irrespective of horsepower and used for hoisting in structural operations or excavating purposes;

This clause defines what is meant by a hoisting plant and includes practically all steam hoists with the exception of those in use at mines or quarries, which latter are exempted by Clause (3) below.

(d) "Minister shall mean member of the Executive Council charged by the Lientenant-Governor-in-Council with the administration of this Act;

(e) "Steam plant" shall mean and include a steam boiler, a boiler and a steam engine and every part thereof and thing connected therewith or used with reference to any such boiler or engine or under the care of an engineer. R.S.O. 1914, c. 170.

(3) Nothing in this Act shall apply to the operation of any steam plant having a capacity of less than 50 horsepower, nor to steam heating plants operating at a pressure of twenty pounds or under, nor to the operation of a locomotive engine or a steamboat or a steamship engine or a hoist at a mine or quarry, nor to boilers used for agricultural purposes. R.S.O. 1919, c. 170.

Clause (3) above defines the exemptions to which the Act does not apply and to which of course graded certificates are not applicable. Power plants having a capacity of less than 50 boiler horse power (determined as in subsection (a) are exempt. Heating plants operating at twenty pounds or under are exempt. Locomotives and steamships are also exempted and boilers for agricultural purposes; threshing engines, etc., also do not come under the provisions of the Act. It should be noted, however, that only hoists which are used at mines or quarries are exempted, all other hoists being subject to the operation of the Act. This clause is re-enacted from the former Act.

(4) The Lieutenant-Governor-in-Council may appoint a Board of Examiners consisting of three competent and independent engineers practically conversant with construction of boilers and the operation of steam plants, who shall hold office during pleasure and who, subject to the regulations mentioned in the next following section shall prescribe the subjects in which candidates for certificates of qualification as stationary or hoisting engineers shall be examined and shall conduct or provide for and supervise the examination of candidates and report thereon to the Minister. R.S.O. 1914, c. 170.

Clause 4 above is the same as that in the former Act and provides for the setting up of the board by which the examinations are conducted. In itself it effects no changes, but in the provisions for setting up regulations which follow important changes have been made which apply to the gading of engineers and to the carrying out of the law.

(5) The Lieutenant-Governor-in-Council upon the recommendation of the Ministry may make regulations for:

(a) The examination of candidates, the granting of certificates, the classifying of these certificates into their respective grades, and the evidence to be furnished by candidates as to previous training or experience and sobriety and good character; and the recording of changes made in engineer's positions;

This section makes provision for the grading of certificates and also for the recording of changes which may be made from time to time in the positions held by engineers.

(b) Determining the time of duration of certificates and their renewal;

(c) Fixing the fees to be paid by candidates upon examination and for certificates and their renewal;

(d) Prescribing the causes for which a certificate may be revoked, cancelled or suspended and for

(e) Fixing the fees or other remuneration to be paid to the members and officers of the board. R.S.O. 1914, c. 170.

(f) Fixing the fees to be paid by plant owners for certificates of registration.

(6) No person shall be eligible for examination unless he is a British subject, or has resided in Canada for at least one year. R.S.O. 1914, c. 170.

7—(1) On the recommendation of the board and on payment of the prescribed fees, the Minister may issue certificates of qualifications to stationary or hoisting engineers, and certificates of registration to plant owners.

(2) Subject to the regulation a certificate may be revoked, cancelled or suspended by the Minister on the recommendation of the board at any time.

(3) Every stationary or hoisting engineer shall, during the continuance of his certificate, register with the board on or before the 1st day of February of each year on a form to be furnished by the board, and any stationary or hoisting engineer who fails to do so shall not continue in charge of a steam plant unless by special permission of the board. R.S.O. 1914, c. 170.

(4) It shall be the duty of all owners of steam plants to advise the board, on a printed form supplied by the board on application, of the B.H.P. and steam pressure of their plants, on receipt of which, together with the prescribed fee, the Minister will issue a registration certificate. Any change made in the plant subsequent to registration will necessitate a re-registration of same.

(5) It shall be the duty of all engineers and firemen who come under this Act to report annually to this board,

on a form which will be supplied, the B.H.P. and steam pressure of the plant which he is operating.

(8) A person who is not the holder of a certificate shall not operate or have charge of any steam or hoisting plant except in case of emergency, when he may be employed in operating any steam plant for a period not exceeding thirty days at any one time. R.S.O. 1914, c. 170.

9. The board at its discretion may grant a provisional certificate to be good for a period not to exceed one year to any person who holds a stationary or hoisting engineer's certificates from the board of examiners or other duly constituted authority of any other Province of Canada. R.S.O. 1914, c. 170.

10. The certificate shall at all times be exposed to view in the engine or boiler-room in which the holder thereof is employed. The registration certificate to be exposed to view in the engine or boiler-room also. Failure to keep such certificate exposed shall be "prima facie" evidence of the lack of qualification under this Act. R.S.O. 1914, c. 170.

11. This Act shall not apply to firemen, who have had less than six months' experience, or other workmen acting under the personal direction or supervision of any engineer holding a certificate under this Act, who is actually in charge of a steam plant, or to the employees of engine builders or steam plant contractors engaged in installing, setting up or testing a boiler or steam plant. This section shall not apply to hoisting engineers. R.S.O. 1914, c. 170.

12. Any person who deems himself aggrieved by the decision of the board may appeal therefrom to the Minister, upon giving such notice as the Minister may prescribe and the decision of the Minister shall be final. R.S.O. 1914, c. 170.

13. The board shall on or before the 15th day of November in every year make to the Minister a report in writing for the year ending on the 31st day of October of the previous year, showing:

(a) The number of certificates granted;

(b) The number of applications for certificates refused and the causes for refusal;

(c) The number of certificates revoked, cancelled or suspended, and the causes for the same;

(d) The amount of fees received from candidates or holders of certificates;

(e) The number of boilers registered during the year;

(f) The amount of fees received from plant owners for registration purposes;

(g) Such other matters as may be directed by the Minister or the Lieutenant-Governor-in-Council. R.S.O. 1914, c. 170.

14—(a) Any member of the board, or inspector, on presentation of authority in writing, signed by the Minister, may enter any premises wherein he has reason to believe there is a steam or hoisting plant and make such inspection as may be necessary to determine whether the provisions of the Act are being complied with.

(b) Any person who interferes with or obstructs a member of the board in the exercise of the powers conferred on him, shall incur a penalty not exceeding $100.

15. Every person who

(a) Except as provided in section 8, operates steam or hoisting plant as the engineer in charge thereof without the certificate required by this Act, or employs or permits any person to operate a steam or hoisting plant as the engineer in charge without such certificate; or

(b) Is guilty of a contravention of subsection 4 of section 7, shall incur a penalty of not less than $10, nor more than $25. R.S.O. 1914, c. 170.

16. It shall be the duty of the inspectors of factories to assist in the enforcement of this Act, to report to the board any violation thereof, and to furnish to the board such information as they may have as to the conduct and capability of any person holding or applying for a certificate. R.S.O. 1914, c. 170.

17. The penalties provided by this Act shall be recoverable under 'The Ontario Summary Convictions Act."

18. "The Stationary and Hoisting Engineers' Act" being chapter 170 of the Revised Statutes of Ontario, 1914; the Act passed in the 4th year of His Majesty's reign, chapter 28; and section 17 of "The Statute Law Amendment Act," 1915, are repealed.

19. This Act shall come into force on the 1st day of January, 1920.

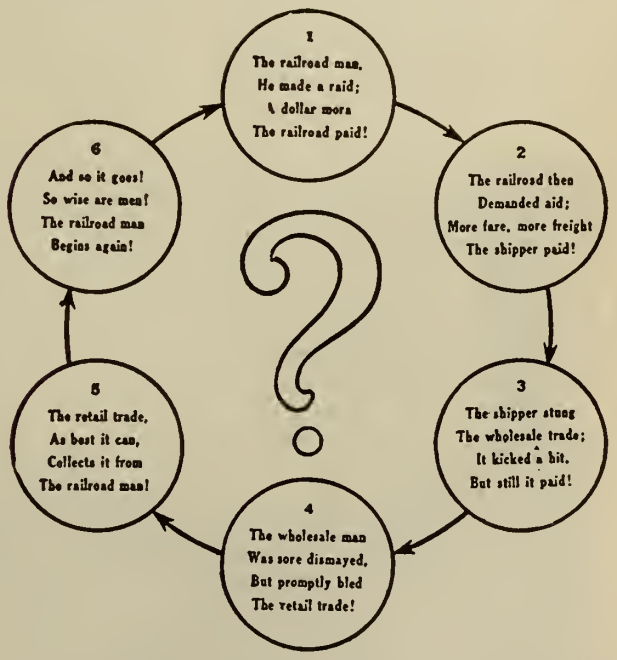
Explantory

Subsection (d) above is to be read in connection with Clause 7, Section 4 below, and applies to the registration of power plants by their owners.

It will be seen that this Act sets up the machinery for the grading of certificates, the registering of plants which come under the Act and the making of regulations for the carrying out of the Act.

That the state may have a sufficient number of tractor drivers to cultivate the maximum amount of land, and so increase the food supply, the California State Board of Education has been conducting emergency classes in tractor operation in the rural districts. The course given lasts three weeks and costs only $2.50. The first week, the students are taught the theory and principle of gas engines; the second week, the assembling and disassembling of tractors, their operation and repair, and the third week they drive tractors in the field.

A service of genuine worth is rendered to its patrons by one automobile manufacturing company. When it is reported to the central factory that a car has been lost or stolen, the factory history is consulted and the car's secret markings collected. In bulletin form these markings are then sent regularly to the company's dealers and garage men, who know that a thief always erases the engine mark but usually overlooks the number on some small, inconspicuous part. In this way the company has been able to recover hundreds of stolen cars in the last few years.



"The vicious circle is infinite; increased wages are over-capitalized for inflated profits, and the cost of goods mounts faster than the wage level."—Statement of the Four Brotherhoods of Railroad Employees. From the New York *Evening Post.*

A Boiler Explosion in a Creamery

The Following Article Reprinted From "The Travelers' Standard" Gives an Interesting Account of a Boiler Explosion. Low Water and Dynamite Are Conjectural Causes for the Accident

THE views presented herewith illustrate a boiler explosion which occurred on June 3, 1919, in a creamery at Hopkins, Michigan. Three men were killed by this accident and four other persons were injured—one of them seriously. The boiler-house was practically demolished, and windows were broken in many buildings throughout the village. The engineer of the plant was one of the men killed, and his death eliminated an important source of information concerning conditions that may have brought about the explosion. Various causes have been conjecturally assigned—among them being the possibility of low water, and the presence of dynamite in the coal bin. So far as we have learned, however, there is not sufficient evidence to support either of these views. Low water is the first explanation that occurs to the average explosion theorist, and if the explosion was violent the opinion that dynamite was present in the coal often finds equal favor.

The information that we have at present is to the following effect: The boiler plant consisted of two horizontal tubular boilers, one of which was 10 years old and the other (the one that exploded) was 35 years old. The exploded boiler was 42 inches in diameter and 10 feet long. The shell was ¼ inch thick and composed of a single course, and the tube heads were ⅜ inch thick. The boiler contained 40 tubes, each 3 inches in diameter. The longitudinal seam was of the double-riveted lap-joint type, with ¾ inch rivets (13-16 inch rivet holes) pitched 2¾ inches between centres. There was no fusible plug in the boiler. The safety-valve was set at 85 pounds, and it is said there was a steam pressure of 55 pounds on the boiler just prior to the explosion.

FIG. 2—ILLUSTRATING THE COMPLETENESS OF THE WRECK.

At about 7.30 a.m. on the day of the accident, an employee went into the boiler-room to see if there was sufficient steam pressure to start the machines, and finding that there was, he returned to the creamery, and was in the act of setting the machinery in motion when the boiler burst. The exploded boiler was thrown about 30 feet to the right of its original position. The tubes from the upper two rows could not be found, with the exception of one tube which lodged in a tree about 400 feet from the original boiler site. The manhole plate was blown about 600 feet. The other boiler in the battery was practically undamaged.

Upon examination it was found that the boiler shell was torn from the top manhole frame down in a diagonal direction to one side of the front tube-sheet, and that this tube-sheet broke across the tube ligaments to the lower handhole opening. The boiler was almost entirely free from scale, and the only evidence of corrosion was about the lower handhole in the front tube-sheet, at which point there had evidently been a long-continued leakage due to a poorly-packed handhole joint. We are told that the metal in the tube-sheet about the handhole was very thin. It is possible, therefore, that the rupture started at this place. In the absence of more definite evidence, however, it is important to remember that when the primary line of rupture runs through the manhole opening, it is often found that this opening was not properly reinforced, or that it was poorly designed or unwisely located. The data at hand do not justify any expression of opinion on these points in the present case.

At the time of the accident several farmers were about the creamery, having delivered cream there, and two of them were killed. The engineer was also killed, as previously stated. In addition, the manager of the creamery had his left leg broken and received internal injuries. Two farmers, and a boy

FIG. 1—GENERAL VIEW OF THE RUINS.

FIG. 3—SHOWING THE FRONT TUBE SHEET.

about fourteen years old, were also cut and bruised by flying debris.

It is stated that the boiler was inspected a short time before the explosion, and found to be in good order. We do not know whether it was insured or not.

TRAINING FOR COMBUSTION ENGINEERS

Undoubtedly, the efforts of the Fuel Administration of the United States during the war to conserve fuel by splendidly organized appeals for greater plant efficiency is bearing fruit in many ways. There seems to be an almost universal interest in the subject of "combustion efficiency" and a growing dissatisfaction with the old regime of indifference to what are now recognized as unnecessary wastes in the boiler room. Everyone recognizes that such conditions were not due primarily to any fault of the men operating the plants. High standards of boiler efficiency were comparatively a new thing. Boiler rooms, as a rule, were in charge of a steam engineer, and his training certainly specialized in the engine room operation to the detriment of the boiler room. Gradually during recent years, through the efforts of consulting engineers and certain pioneers in the combustion field, standards of efficient boiler room practice have crystallized so that principles are as well understood and methods as clearly defined as at the other end of the steam plant. It is seen that the subject of combustion must be studied and mastered by itself as a specialty; that there is a place for the combustion engineer just as for the steam engineer. In fact, every steam engineer should be a combustion engineer.

The principal reason that there have been so few combustion engineers has been the lack of adequate courses of training, the subject having been handled only as part of courses in steam engineering.

The demand for a training in combustion engineering has been recognized by Joseph W. Hays, whose contributions on combustion subjects have frequently appeared in these columns. It has remained for him to organize the Hays School of Combustion, with offices at 190 North State Street, Chicago. The purpose is to give a complete training in combustion efficiency through the mails and to graduate combustion engineers from the ranks of steam engineers and boiler room men who are able to do the necessary reading without interfering with their regular work.

The Hays school is also laying stress on the possibility of advanceent for any young man who is not afraid to tackle the disagreeable features of the job of fireman, taking up at the same time the correspondence course in combustion. The boiler room is the best place for him to apply and work out what he learns along combustion lines, and when he graduates as a combustion engineer he has a fine outlook ahead to pay him for the apprenticeship he serves, shoveling coal and wheeling ashes.

Mr. Hays has associated with him, as reviewing and advisory editors, some of the best talent among combustion men in the country, who have contributed their services and endorsement to the course for the good of the cause. The names of Joseph Harrington, Ferd R. Low, David Moffat Myers, Professor S. W. Parr, and Arthur L. Rice would seem to promise everything for the success of the school and the high standard of its teaching.

An enormous gas cloud gathering on the sun forms an arc 340,000 miles long on the edge of that body, astronomers say. It is about 125,000 miles away from the edge, and the distance from the sun to the top of the cloud is estimated to be 200,000 miles.

GENERAL MITCHELL AT ELECTRIC CLUB

In his talk at the Electric Club luncheon, Toronto, on Friday, Sept. 26, Brigadier-General C. H. Mitchell dealt with the importance of the engineer in warfare. The man who had engineering, mechanical or electrical experience had the advantage over all others; not only because of the application of his training to engineering problems, but also because of the fact that his type of mind and the training it had received, fitted him for the handling of men and the solving of problems in everyday warfare. The speaker felt sorry for the lawyer chap, for he had nothing in his daily work similar to what he had been accustomed to. The engineer, on the other hand, had an experience which prepared him for all the hard work, long hours, intense application, particularly on staff work, which made him valuable.

In opening his address, the speaker paid tribute to the telephone and telegraph systems in use in the army. In Sir Herbert Plumer's Second British Army, of which General Mitchell was head of the intelligence staff, the normal number of telegrams received at headquarters daily was 2,000, while the telephone service was so greatly used that it was necessary at times to limit the service. The psychology of the German was one of the most interesting things in the whole war to the speaker, and the game of matching wits with the foe was fascinating beyond measure.

The enemy artillery before the war had been located by observers, but this was soon got away from when the great war settled down to trench warfare. It became a steady everyday business. Even if a gun was down below a hill the rays of the flash could be seen rising above the hill. The synchronization of these flashes by several observers was useful under certain weather conditions, but the French evolved a method whereby with microphones, equidistant on a long arc, acting like telephone receivers, when a gun started to fire, the first microphone picked it up, registered it on a film, and so on through the series, so that the length of time elapsing gives him the several triangular bases. This method worked better in a fog, but not in adverse winds, and would locate a gun within 25 yards at a distance of 6,000 yards.

Further experiments in these methods will be carried on at the University of Toronto by two officers who have had experience in France and are now on the staff.

Practically all the munitions made in Italy were manufactured by Hydro-Electric power. The Austrians captured some of the largest installations on the Venetian plain when the line broke. The Italians are most expert electricians, but since 1906, when he first visited Italy, he had seen many things in Italy which had been adopted from developments brought about by Canadian engineers. He believed that all over the world there would be seen many important developments, the result of war experiences.

High-Pressure and High-Temperature Steam

The Following Paper Read Before the Institution of Electrical Engineers Gives Some Interesting Engineering Data Regarding One Trend of Power Plant Development and Design

By J. H. SHAW

ALL engineers responsible for the generation of power by steam are seeking more economical methods by which the energy contained in the coal can be converted into energy of a more convenient nature. The power required may be in the form of electrical, hydraulic, or mechanical energy; the most important to the majority of the members of this institution is the first named, and this paper is written principally from the point of view of the engineer interested in the generation of electricity.

With the use of steam as a medium for carrying the heat contained in the coal from the boiler to the prime mover, it is unfortunate that, with the present knowledge of thermodynamics, the greater part of the heat in the coal is lost—a comparatively small portion up the chimney and the greater portion in the circulating water, via the condenser.

It may be possible in the future to eliminate some of this loss by the use of a substance, other than water, which will require less heat to convert it into gas. As an alternative, the gas turbine may offer the solution. As these alternatives have not yet approached the commercial stage, engineers are, for the time being, compelled to focus their attention on increasing the economy to be effected by means of plant using water as a heat conveyor.

It is apparent that in order to increase the heat efficiency of a steam plant, whose characteristics are that a constant loss is inevitable whatever the temperature and pressure, it is necessary to increase the working range of temperature and pressure.

The upper limit is perhaps the temperature at which metals rapidly lose their strength, and the erosive effect which the very hot steam will have on the blading of the turbine. The lower limit is generally decided by the locality of the power station. A works equipped with cooling towers cannot expect to obtain a lower bottom temperature than 75° F., and this only when the towers are amply proportioned and the ground space is not limited. A bottom temperature of 80° F. is more to be expected, which will give 28 inch vacuum or 2 inch absolute pressure. A power station located near a cold river or the sea, where the temperature of the water during the greater part of the year is approximately 55° F., can efficiently be equipped with condensing plant designed for 29.1 inches of vacuum, i.e. 0.9 inch absolute pressure.

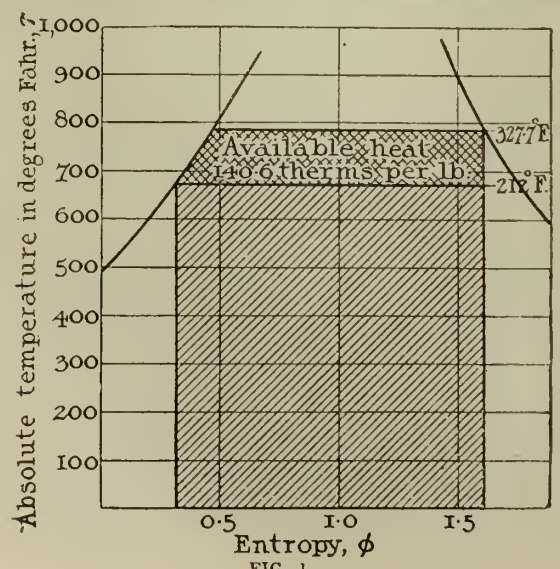


FIG. 1.

With cooling water at a temperature of 60° F. condensing plant for vacua between 28.5 and 28.8 inches can be installed.

There is little doubt that the majority of power station engineers have given attention to the efficient utilization of steam at the lower ranges of temperature and pressure, and have been during the past few years considering the

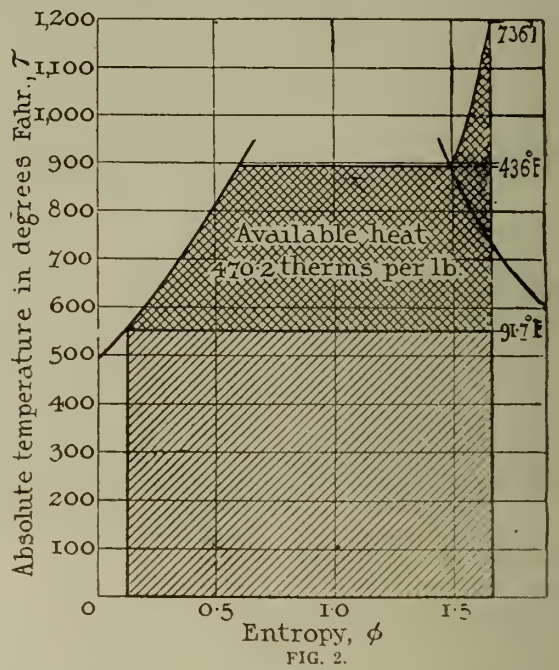

FIG. 2.

upper range. Here there is rather more scope for choice, but it appears that doubt exists as to whether it is the more economical to increase the temperature of the steam by superheating or to increase the range by the use of higher pressures and a moderate amount of superheat. This question has been shelved to a certain extent owing to engineers being engaged on war work, and thus unable to give the necessary time and attention to developing plant suitable for the higher ranges.

An interesting plant has been installed by the British Thomson-Houston Company at their Rugby power house, consisting of a B.T.H. turbine and a Babcock and Wilcox marine type boiler, capable of a normal evaporation of 18,000 lb. per hour with feed water at 80° F. (the working pressure being 350 lb. per square inch, the final temperature of the steam after passing the superheater 700° F., and the test pressure of the boiler 525 lb. per square inch). Good results have been obtained from the combination, and an inspection of the machine after about a year's operation showed no undue signs of wear.

At the Carville power station, Newcastle-on-Tyne, the latest section of the boiler house is designed for 275 lb. pressure, and at Glasgow the boiler pressure at the new works is to be 250 lb. per square inch.

A question that will appeal to all is "Will it pay?"

A good case can be made out for a jump to 600 lb. pressure with a total temperature of 700° to 800° F., but this will involve a considerable amount of development charges being borne by the undertaking or undertakings which are the first to adopt such a pressure. On the other hand, it appears that practically all designs of existing apparatus can be so modified as to admit of

pressures of 350 to 400 lb. per square inch. It would, therefore, seem that to increase the working range of steam without the development of new designs a pressure of 350 lb. can safely be adopted, and that if it is decided to increase the range the adoption of a pressure below this is akin to "hedging" the question.

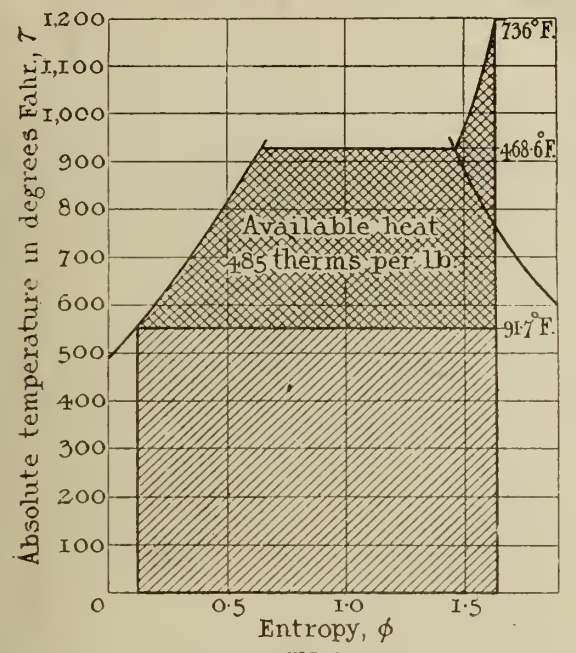

FIG. 3.

When considering any results of tests on high-pressure or high-temperature steam generating plant, it is essential that the tests on the boiler side and the tests on the turbine side be studied separately; further, it must be remembered that any results obtained on an extra high pressure boiler can be obtained and, considering the boiler pressure from the economizer, surpassed on a similar and similarly equipped low-pressure boiler.

By the aid of the temperature entropy diagram the gain due to increasing the working pressure and temperature ranges of the substance can be shown with advantage. Assuming frictionless adiabatic expansion, Fig. 1 shows the amount of heat available in 1 lb. of dry saturated steam at a pressure of 100 lb. per square inch absolute (327.7° F.) expanding to 14.7 lb. per square inch absolute (212° F.) and is equivalent to 140.6 therms per lb. Figs 2 and 3 represent the heats available per lb. of superheated steam expanding from 365 lb. per square inch absolute (736.4° F.) to 1.5 inches (mercury) absolute pressure (91.6° F.) and 500 lb. per square inch absolute (736.4° F.) to 1.5 inches (mercury) absolute pressure (91.7° F.). The amounts of heat available are 470.2 therms and 485 therms per lb. of steam respectively.

The "Mollier" diagram, by means of which problems in adiabatic expansion can be graphically solved, has total heat as ordinates and entropy as abscissæ. True isentropic or unresisted adiabatic expansion involves no change of entropy, and would be shown on the diagram by a straight vertical line. As an example, assuming that steam is to be expanded adiabatically from 200 lb. per square inch absolute saturated to 1 lb. per square inch absolute, the amount of heat in the steam before expansion can be read directly off the chart or obtained from tables in regard to steam, the value being 1,205.4 therms. Following vertically down the chart until the pressure line 1 lb. per square inch is reached, it will be seen that the amount of heat still remaining in the steam is 866.70 therms, and that the steam is 76.5 per cent. dry. Subtracting the latter value from the former, 1,205.4 — 866.7 = 338.7 therms, gives the heat drop or the number of therms available between the ranges above specified. As another example, with steam at 350 lb. absolute and superheated 250° F. and at a total temperature of 682.4° F., the initial heat is 1,361.2 therms, the final heat amounting to 922.5 therms at 1 lb. per square inch absolute; the heat drop in this case is 438.5 therms. Comparing the two examples, it will be seen that there is a gain of 99.8 therms per lb. of steam or water, or 29.5 per cent. increase in available heat in steam at the higher temperature and pressure over the lower pressure, while only 12.9 per cent. extra heat units were used in raising steam at the higher pressure over that required at the lower pressure.

The expansion that takes place in a steam turbine is not isentropic and is usually called adiabatic and resisted. Due to the friction, reheating takes place during the passage of the steam through the nozzles and blades, and the mixture gains in entropy. The amount of this gain can be calculated with considerable accuracy by turbine designers, and approximately by the user. Mr. Goudie, in his book on "Steam Turbines," has calculated a series of curves by which he arrives at the "reheat factor"; these curves are reproduced in Fig. 4, and can be used for multi-stage turbines and pressures between 150 and 200 lb. per square inch. The curves are likely to be low for higher steam pressures.

For a comparison between the cost of running a power station at 200 lb. pressure (gauge) and at 350 lb. pressure, Schedule 1 has been prepared. It is proposed to consider a riverside station, where the water is suitable for surface condensing. It is proposed to install 20,000 k.w. sets, and coal is assumed to be within a reasonable distance; the cost of the coal, with a net calorific value of 10,000 therms per lb., is for the purpose of the schedule assumed to be 10s. per ton at the works. The incombustible contents of the coal would amount to 20 per cent. The average water temperature is taken to be 60° F., and the vacuum 28.5 inches, with the barometer at 30 inches. The overall efficiency of the boiler house plant is assumed to be 77.5 per cent., which should be obtained with modern boiler control.

Turbine makers are not all in accord as to the efficiency to be expected from turbines of the size under consideration when working on high pressures. A well-known firm states that between 200 lb. pressure and 350 lb. pressure there will be a drop in ratio efficiency of 2½ per cent.;

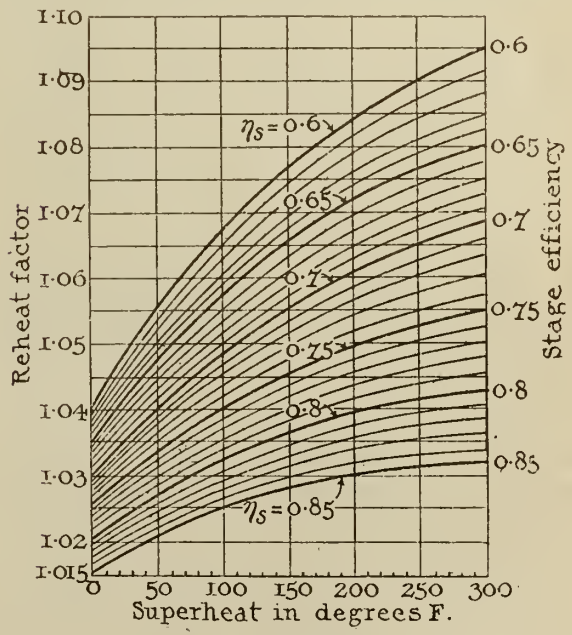

FIG. 4.

other manufacturers state that a turbine can be built with the same efficiency at 350 lb. pressure as at 200 lb. There is no doubt that the increased density of the steam at the higher pressure will increase the internal losses in the turbine.

Martin, in his book entitled, "Design and Construction

SCHEDULE 1.

ABSOLUTE PRESSURE AT TURBINE EXHAUST, 1·5 IN. (HG.) (91·7° F.). CONDENSATE TEMPERATURE, 85° F

Steam Pressure at Turbine	215 lb. per sq. in (abs.)					365 lb. per sq. in (abs.)						500 lb. per sq. in (abs.
Superheat of Steam at Turbine, ° F.	100°	150°	200°	250°	300°	50°	100°	150°	200°	250°	300°	268°

of Steam Turbines," gives Dr. Lasche's formula for the power absorbed by rotating discs as—

$$\text{Power absorbed in kilowatts} = \frac{A}{5.5}\left\{\frac{\text{r.p.m.}}{1{,}000}\right\}^3 \frac{d\,l}{V}.$$

d = diameter of wheel in inches;
l = average length of blades in inches;
V = specific volume of the steam;
A = a constant.

The constant is unity for a wheel carrying one row of moving blades, and 1.2 for wheels with two rows. The formula is said to be valid for wheel diameters from 35 inches up to 47 inches, and for values of l ranging between ¾ inch and 2 inches.

The author above quoted further states that "the resistance offered by a turbine wheel when at work is, however, quite different from its resistance when motored round; with a wheel at work and with complete admission there is no true windage due to the blades, whilst with partial admission the blades on the active arc are also free from windage."

In view of the above and the difference between the views of experts, it will be advisable to look ahead and anticipate that the efficiencies of turbines of the size under consideration will be improved in the near future. For the purpose of the calculations a turbine ratio efficiency of 80 per cent. is assumed, at both 200 lb. pressure and 350 lb. pressure with the steam superheated 150 degrees F. and a constant vacuum of 28.5 inches. The corrections used for obtaining the consumptions at different steam temperatures are taken from Mr. Baumann's paper, Journal IEE, 1912, vol. 48, p. 768. An alternator of 20,000 k.w. capacity can no doubt be built to give an efficiency of 97 per cent. at unity power factor, thus making the turbo-generator ratio efficiency $0.80 \times 0.97 = 77.6$ per cent. Assuming bearing and other friction losses to absorb 2 per cent., the internal efficiency of the turbine will amount to 82 per cent.

Schedule 1 shows the comparisons of coal, steam, and heat consumptions for a 20,000 k.w. machine running under the conditions mentioned, at 200 lb. and 350 lb. pressure by gauge at varying superheats; also at 500 lb. pressure absolute and 268 degrees F. superheat, at which pressure and superheat the total temperature will be 736.5° F., which is about the maximum temperature at present recommended for the materials now being used in turbine construction. Schedule 1 shows that the cost for coal when generating 175.2 million k.w. hours with a load factor of 100 per cent. will be £64,400 at the higher pressure (superheat 250 degrees F.), and £69,200 at the lower pressure with corresponding superheat. This is a saving of £4,800 per 175.2 million k.w. hours, or 0.007 pence per kilowatt hour. Unfortunately, a load factor of 100 per cent. is impossible, and the conditions under which power stations are operated must be considered before even an approximate estimate of working costs can be arrived at.

An annual load factor of 50 per cent. may mean full load for half the number of hours in a year, or anything between this and half load for the full number of hours in the year.

In order to avoid having to assume a curve of load and the necessity of calculating the consumptions at partial loads, a method of computation generally adopted for calculations of this nature, and one which is sufficiently accurate for this purpose, is to assume that the

ratio of the station output to the total coal consumed is in accordance with Williams' law, that is, a straight line.

Fig 5 is plotted from results obtained at the Bradford Corporation's Valley road power station for a number of days during the year 1917. On this curve the weight of coal used is shown to be 60,000 lb. per day plus 2.32 lb. per unit generated. The quantity of coal per day, that is, 60,000 lb., is the no-load consumption of the work and will include the no-load consumption of one turbo-generator. In order to make the calculations as simple as possible, it is proposed to deduct the no-load consumption of one machine (5,500 lb. of steam per hour) from the works' no-load consumption, and to assume an evaporation of 6 lb. of water per lb. of coal, and to call the figure so obtained the works' standing loss.

$\frac{60{,}000 \times 6}{24}$ = No-load consumption of works in lb. of steam per hour = 15,000 lb. of steam per hour

Deduct the no-load consumption of one machine

$= 15{,}000 - 5{,}500 = 9{,}500$ lb. of steam

and $9{,}500 \div 6 = 1{,}583$ lb. of coal per hour.

To arrive at an estimated figure for the power stations under discussion, it is proposed to assume that the standing loss of the station designed for 200 lb. will be the

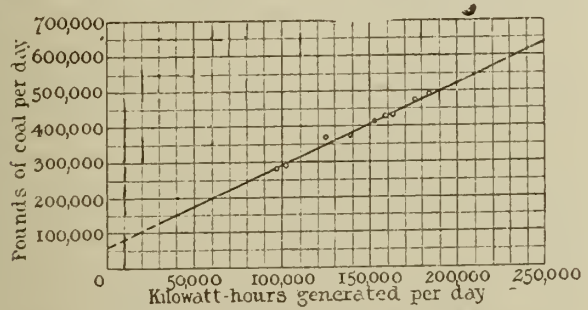

FIG. 5—STATION CONDITIONS—185 LB. PER SQ. IN. (GAUGE); 100 DEG F. SUPERHEAT; 28 IN. VACUUM; 30 IN. BAROMETER.

same as for the Valley road power station, that is, 1,583 lb. of coal per hour. It will be fair if the same basis is taken for the plant at 350 lb. pressure, with 8 per cent. added to the works' standing loss, representing roughly the higher temperature of the steam at the higher pressure. Standing losses must be approximately proportional to the top temperature, as this affects radiation, boiler exit losses, etc.

For a 20,000 k.w. set the no-load consumption will be approximately 22,000 lb. of steam, or 3,666 lb. of coal per hour. These figures plotted in conjunction with the steam consumptions shown in Schedule 1 give the total steam consumption at any load as

22,000 lb.+9.54 lb. of steam per kilowatt hour

for the plant operating at 200 lb. pressure, and

22,000 lb.+8.6 lb. of steam per kilowatt hour

and 3,729 lb.+1.45 lb. of coal per kilowatt hour for the plant operating at 350 lb. pressure and 250 degrees superheat.

In order to allow for changing over, for the period when two or more machines are temporarily running together at partial loads, for reduced efficiency in the boiler house due to adverse circumstances, and for the necessity of sometimes running the plant when it is not in the best condition, it will be advisable to add 5 per cent. to the figures obtained for the load consumption and 5 per cent. to the no-load loss of the turbine, thus making the consumptions and costs as below:—

	Maximum load of 20,000 k.w. and 50% load factor 87.6 x 106 units per annum.	
	200 lb. Pressure, 250 deg. Super-heat, 28.5 in. Vacuum	350 lb. Pressure, 250 deg. Super-heat, 28.5 in Vacuum
Works standing loss in tons of coal	6,200	6,700
No-load consumption of turbo-generators in tons of coal	15,100	15,314
Load consumption of turbo-generators in tons of coal	65,300	59,867
Total	86,600	81,881
Lb. of coal per unit on station busbars	2.211	2.094
Total cost at 10s. per ton	£43,300	£40,940
Cost of coal per unit	0.119d	0.1122d

A further Schedule (No. 2) has been prepared, showing comparative coal costs of riverside stations working at

200 lb. per sq. in. (gauge), 300 deg. F. superheat, and
350 lb. per sq. in. (gauge) 250 deg. F. superheat, and
485 lb. per sq. in. (gauge), 220 deg. F. superheat

All the efficiencies and calorific values used in preparing Schedule 1 are used in preparing the Schedule above mentioned, so that they are directly comparative.

Schedule 2

Steam pressure at turbine, lb. per sq. in. abs.	215	365	500
Superheat of steam at turbine, °F.	300	251.6	219.4
Total temperature of steam at turbine, °F.	688	688	688
Totalheat of steam(from 32 °F),therms per lb.	1371.2	1,363.2	1,356.0
Absolute pressure at turbine exhaust, in.(Hg.)	0.9	0.9	0.9
Heat drop per lb. of steam, therms	454.9	480.7	495.4
Ratio efficiency of turbine and alternator	79.5%	79%	78.6%
Internal efficiency of turbine	84.0%	83.4%	83.0%
Steam consumption of turbine, lb. per kw.-h.	9.46	9.00	8.77
Total steam consumption of turbine, lb. per hour	187,600	180,000	175,400
Heat rejected to condenser (from 32° F.), therms per lb.	985	962	945
Ratio of circulating water to steam condensed	81	80	77
Circulating water quantity, gals. per hr.	1,520,000	1,460,000	1,350,000
Power for circulating pumps, b.h.p.	240	230	215
Power for air and condensate extraction pumps, b.h.p	92	90	88
Power for boiler feed pumps, b.h.p.	84	133	180
Power for induced draught fans, b.h.p.	197	187	182
Power for small auxiliary motors, b.h.p.	62	64	66
Total power for auxiliaries, b.h.p.	675	704	731
Total power for auxiliaries, k.w.	560	580	605
Nett kilowatt output to busbars	19,440	19,420	19,395
Heat in steam from temperature of hotwell, therms per lb.	1,331.2	1,323.2	1,316
Steam consumption per effective kw.-hr., lb.	9.74	9.48	9.04
Lb. of steam evaporated and superheated per lb. of coal	5.83	5.86	5.89
Coal consumption per effective kw.-h., lb.	1.67	1.62	1.536
Coast of coal at 10s. per ton, generating 175.2 x 10.6 k.w.-h.	£65,200	£63,300	£60,100

Schedule 3

	215 lb. per sq in. abs., 250 deg. F. Superheat, 28 in. Vacuum	365 lb. per sq in. abs., 250 deg. F. Superheat, 28 in. Vacuum
Total heat of steam (from 32° F.), therms per lb.	1,345.0	1,363
Heat drop per lb. of steam, therms	401.3	441.6
Ratio efficiency of turbo-alternator	79%	78.9%
Steam consumption per kw.-h., lb.	10.75	9.85
Heat rejected to condenser, therms per lb.	1,011.5	996
Ratio of circulating water to steam	63.5	62
Power for circulating pump, b.h.p.	432	385
Total power required for auxiliaries, kw.	730	700
Lb. of steam per kw.-h. on busbars	11.1	10.2
Lb. of coal per kw.-hr. on busbars	1.79	1.675
Cost of coal at 10s. per ton per 175.2 x 10.6 kw.-h.	£70,000	£65,200

Circulating water at 80° F. discharged from condenser at 96° F. Efficiency of boiler house, 77.5 per cent. Coal with a net calorific value of 10,000 therms per lb.

The head against which the circulating pumps have to work is taken to be 50 feet.

Schedule 4

Steam pressure at turbine, lb. per sq. in. ab.	215	265	315
Total temperature of steam at turbine, °F.	688	688	688
Superheat at turbine, °F.	300	281.6	265.6
Total heat of steam (from 32° F.), therms per lb.	1,371.3	1,368.6	1,365.9
Absolute pressure at turbine exhaust, in.(Hg.)	1.5	1.5	1.5
Heat drop per lb. of steam, therms	429.2	440.3	449.1
Ratio efficiency of turbine and alternator	79.5%	79.1%	79.0%
Steam consumption of turbine, lb. per kw.-h.	10.023	9.82	9.65
Total steam consumption of turbine, lb. per hour	200,460	196,400	193,000
Steam consumption per effective kw.-h., lb.	10.3	10.10	9.94

Schedule 3 shows the coal required, and power for auxiliaries, for a cooling tower station working between 200 lb. per sq. in. gauge, 250 degrees F. superheat, and 350 lb. per sq. in. gauge, 250 degrees F. superheat exhausting against a back pressure of 1 lb. absolute pressure.

Schedule 4 gives the relative steam consumptions with steam at a temperature of 688° F., 215 lb. per sq. in. gauge, 265 lb. per sq. in. gauge, and 315 lb. per sq. in. gauge, exhausting against a back pressure of 1.5 inches of mercury or 28.5 inches vacuum.

The foregoing relates only to the cost of coal; the remaining items which make up the total works' costs are not likely to be affected by the use of higher pressures and temperatures. Oil, waste, and water are practically unaffected; repairs and maintenance may be increased, but not to appreciable extent. The capital cost of the plant is an item that may be affected to a considerable extent, but unfortunately the increased cost of turbines, boilers, pipes, etc., due to the use of higher pressures and temperatures cannot be given in a paper of

Steam Pressure ..	215 lb. per sq. in. abs.)					365 lb. per sq. in. (abs.)						500 lb. per sq. in. (abs.)

this description. At a time like the present, when all manufacturers are experiencing difficulties in maintaining deliveries of standard articles, it is not to be expected that they will go into costs of special apparatus. Further, with the continued increases in wages, the cost of transportation, and the cost of raw material, it is almost impossible accurately to estimate any costs that are to remain good for a length of time. Whereas before the commencement of the war a 5,000 k.w. turbine, alternator, and condenser could be purchased for £2.9 per kilowatt, a machine of 20,000 k.w. capacity now costs £4.1 per kilowatt.

With regard to the practical difficulties, it is but to be expected that before pressures of 500 lb. or 600 lb. per square inch are adopted, a radical departure will have to be made in present boiler construction. All square boxes and headers will be eliminated, the drums and tubes will be smaller in diameter, and the design of the boiler made more elastic. The type of boiler will no doubt assume the appearance of a flash boiler, with practically no steam or water reserve, and fired by gas on the surface combustion principle.

For more moderate pressures, up to 350 lb. per square inch, the existing type of boiler can be modified and successfully used. At Carville power station Babcock & Wilcox marine type boilers are being used, at 275 lb. per square inch gauge pressure, and at the British Thomson-Houston Company's works at Rugby a Babcock & Wilcox boiler is installed and successfully working at 350 lb. per square inch. Further, Messrs. Babcock & Wilcox state that they have at present two boilers on order for a working pressure of 475 lb. per square inch with steam superheated to a final temperature of 700° F., and that they are quite prepared to supply boilers in their ordinary business for such pressure and superheat.

With higher steam pressures the temperature of saturation is raised, and, due to this, greater care must be exercised in the quality of the water used for the boiler feed. A feed water that is perfectly satisfactory at 380° F. in a modern tubular boiler might be quite unsuitable for use in a flash boiler. The quantity of air, CO_2, and oxygen will have to be kept down to a minimum, and also the non-soluble salts which are generally in the water discharged from an ordinary lime-soda water softener. A natural development, and one which is already taking place, is to heat the feed water under atmospheric pressure by means of live or exhaust steam in order to drive off the entrapped and dissolved gases as much as possible. According to the table on page —, extracted from Lunge's "Technical Chemist's Handbook," it is necessary to raise the temperature of the water to 100° C. before the quantity of air in the water is appreciably reduced.

The source of water for use in high pressure plants will have to be carefully traced, and the treatment of the water should be such that a minimum of unsoluble salts remains in it after treatment. The purer the water the greater affinity it has for air, CO_2, and oxygen, and every care should be taken that it is not exposed to the air between the condenser and the boiler. In order to avoid such exposure to the air it is suggested that the feed pump should be an extension of the condensate pump and the condensed water pumped direct into the feed line.

The natural development of the turbine for higher pressures appears to be in a line with a Parsons two-cylinder machine, with a flexible claw-type coupling between the cylinders and a thrust bearing for each cylinder. For very large sets, above 50,000 k.w., the cross-compound turbo-generator will no doubt be used, the high pressure turbine being attached to a generator and the low pressure turbine to another generator. Each set can then be run at its most suitable speed, with resulting high efficiency. This arrangement will no doubt lead to reheating the steam after it leaves the high pressure turbine and before entering the low pressure machine. Dr. Ferranti has already done valuable work on this subject, the results of which have unfortunately not been published.

The design of the condensing plant is not likely to be modified because of the use of high pressure or high temperature steam, but it must not be lost sight of, that with steam initially at the same temperature but at different pressures the plant using the high pressure steam will reject less heat units to the condenser per lb. of steam used in the turbine.

The steam pipes to be used in a station where both high pressures and high temperatures are employed will have to be very carefully designed.

A well-known tube firm on being asked their opinion as to the difficulties to be experienced with steam piping have replied that:—

"The thickness of both the tube and flange would vary slightly in accordance with the pressure. We should certainly recommend the tubes to be of our lap welded process with flanges welded on, and in both cases the gauge of the piping and the thickness of the flange would naturally be increased according to the pressure to contend with.

"With regard to jointing material, we would suggest that corrugated rings and fibrine jointing compound would

Solubility of Gases in Water

*Winkler. †Bohr and Bock.

be most suitable and, for preference, for high temperature a nickel ring. Steel bolts to be used and not wrought iron.

"Regarding the temperature of 800°, we have had practically little experience of such a high temperature, but quite frequently we supply tubes for a temperature of 700° and, as far as our knowledge is concerned, we have not found that this high temperature has been the cause of any undue shortening of the life of the pipes; in fixing the thickness of mains, however, the reduction in tensile strength through the increase in temperature would, of course, be kept in view.

"As far as we can see, one of the principal difficulties with this high temperature will be with expansion, as the pipes will be thicker and naturally more rigid, so that it will be necessary to lengthen the expansion bends or any natural bends which are taking up expansion in order to meet the additional expansion in the mains, and therefore this point will have to be carefully considered in designing installations.

"The points of anchorage will have to be very carefully watched, as invariably in boiler houses there is nothing very substantial to anchor off at the essential points."

The question of expansion at higher temperatures will be of the utmost importance. For example, take the case of a steam pipe 100 ft. in length, and assume that the pipe had been erected at 60° F. It will be found that at a temperature of 388° F., equal to steam at 200 lb. gauge saturated, the expansion is 2.59 inches, while at 786.6° F., equal to steam at 600 lb. pressure and 300° F. superheat, the expansion is 5.75 inches.

The expansion given can be readily taken care of if the designer can ensure that the expansion would always take place lengthwise in the pipe range. Unfortunately, taking a boiler off a range will cause a considerable cross-strain to the main header, due to the connecting pipes cooling down and contracting.

It appears that the main steam connections of the boiler will have to be designed in a flexible manner, in order to relieve the main range of stress. Further, these connections should be of the manifold or header type, that is, made up of many small pipe connections.

The specific volume in cubic feet per lb. of steam at approximately 800° F. and at pressures of 200 lb., 350 lb., and 600 lb. by gauge, are 3.47, 2.10, and 1.25 cubic feet per lb. Unfortunately the relative areas of the steam pipes cannot be reduced proportionately to the specific volumes, as the friction of the denser steam would cause undue pressure drop. Proportioned according to the density of the steam, a pipe to supply a 20,000 k.w. set could have a diameter of 12 inches at 200 lb. gauge and 800° F. total temperature, and a diameter of 7.25 inches at 350 lb. pressure and 800° F. superheat, with a velocity of approximately 150 ft. per second. In actual practice the diameters would approximate to 14 inches and 10 inches for 200 lb. and 350 lb. respectively.

There is no doubt that a large portion, in fact the major part, of the pressure drop in steam pipes as at present erected is due to the method of arranging ring mains and duplicate paths for the steam when certain parts of the main are down for joint making, and the provision of a duplicate path often so spoils the design that joints cannot be kept tight.

If the piping is designed on the unit principle, that is, a number of boilers practically isolated on to one generating unit, a small equalizing main only need be provided at the end of the boiler house. Ample arrangements can be made for expansion with such an arrangement, and drainage is required at two points only in each section. at the turbine steam separator and in the equalizing main. It could be arranged that steam would never enter or leave a pipe at right angles, and each branch would enter the main pipe at an angle of approximately 45 degrees.

From inquiries it is apparent that the boiler mounting and valve makers are quite alive to the possibilities of high-pressure and high-temperature steam coming into commercial use. One well-known firm reports:

"The highest steam pressure for which we have made valves is 400 lb. per square inch, and we are prepared to make the same for pressures up to 600 lb. per square inch.

"The highest temperature for which we have supplied valves is 700° F.

"The highest velocity in steam practice that we have met is 230 ft. per second."

They further state that with the limits mentioned above they have not found that high superheat has a detrimental effect upon steel or their non-ferrous alloy, which is used for the internal working parts of valves of their manufacture.

It is well known that cast iron when subjected to high temperature undergoes changes which in time causes it to distort and grow; there is also a chemical action taking place which causes the material to disintegrate and finally break away.

A 10-in. valve with a cast steel body and cast iron disc and seat, which was in service at the Bradford Corporation Valley road power station for 8 years, had to be taken out of commission on account of the valve grooving and breaking. This valve had not at any time been subjected to a higher temperature than 480° F.

An American firm reports as follows:—

"The increase of steam pressures above 200 lb. for commercial purposes has received impetus only during the last few years, and for that reason there is not a wealth of data to offer.

"It has been apparent to us for some time back that the trend of the engineering world was towards increased pressures and temperatures, and we have provided the market with material to meet the new requirements.

"We have designed a line of cast steel gate valves and special fittings for 400 lb. steam working pressure and total temperature of 800° F., and can furnish material for any steam pressure containing no greater temperature than above mentioned.

"It is not so much a question of pressure in the designing of a good valve or fitting as it is the temperature to which it can be subjected. It is a recognized fact that metals such as cast steel, cold rolled steel, nickel steel, and monel metal which are used in the manufacture of this class of material, show a decrease in elastic limit when temperatures higher than 750° F. are reached. The reduction of strength of the metal above 750° F. can, in a measure, be compensated for by proper design and liberal distribution of material, but other elements such as weight of piping, expansion and contraction, settling and water hammer must also receive serious consideration. The packing and gasket problems are also worthy of thought."

The question of the use of higher pressures is quite appreciated by the makers of economizers, who are prepared to manufacture economizers for 350-lb. boiler pressure or higher, either of their standard design, with the details modified, or of a design suitable for use as an integral part of the boiler, if necessary with horizontal and mild steel tubes.

General

It must be admitted that in order to attain a higher overall efficiency it is necessary to increase both the pressure and the temperature of the steam. An increase of pressure with a constant temperature would mean that the dew point is carried further up the turbine towards the high pressure end, thus tending to accelerate blade erosion in the lower stages and a reduced stage efficiency of the turbine. Also the high pressure blading of a turbine is considerably less efficient than the low pressure stages, and although the losses in the high pressure end are partly recovered in the low pressure blades, it is apparent that to assume that a turbine for extra high pressures can be built with the same efficiency as one for a lower pressure (within limits) is taking a hopeful view, and that there is justification for hesitation before adopting extra high pressures on the part of managers responsible for the financial results of large undertakings.

Firing Steam Boilers With Powdered Coal

The Following Article Gives an Account of Actual Test on Boilers Using Pulverized Fuel

IN the accompanying illustration may be seen a twin unit of the carburization process installed on 150 horsepower horizontal return tubular boiler. The director of the United States Bureau of Mines has stated that fully half a billion dollars were wasted in one year through the inefficient use of coal. It has been estimated that sixty-one per cent. of the coal mined in this country is used for power production in steam boilers in industrial plants and railroad locomotives. Taking the annual coal consumption for the United States as 500,000,000 tons, we find that approximately 305,000,000 tons are used for various steam power purposes. The use of coal for domestic purposes and small steam trade amounts to 16 per cent., or 80,000,000 tons.

Coal for coke making takes 13 per to 16 per cent., or 80,000,000 tons.

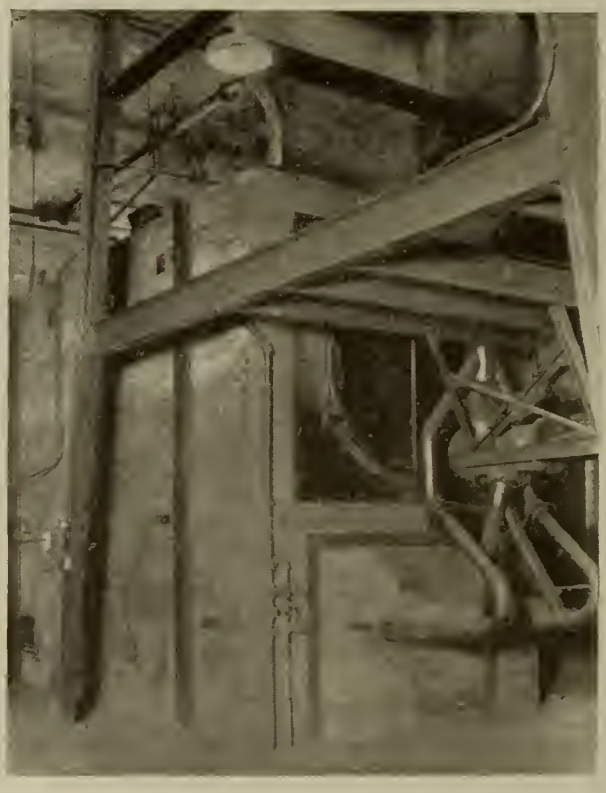
Coal for coke making takes 13 per cent.; exports, 4 per cent.; 2 per cent. is used at the mines: steamship bunker coal amounts to 2 per cent., and 1 per cent. is consumed in the manufacture of coal gas. It is indeed a matter of interest to know how much of this coal might be saved provided the boiler operators were made familiar with the conditions of most efficient firing and utilization of coal.

The preventable waste of fuel in the boiler furnaces of one steel mill amounted to 40,000 tons per year, which, at $5 a ton would cost $200,000. This was a comparatively modern plant. The efficiency of boiler and furnaces in a 14-day test was 55 per cent. The load factor was unusually favorable to high efficiency and could readily be raised to 70 per cent. or over.

Engineers advocating the use of powdered coal urge that, standing on the eve of what is to constitute the greatest revolution in the utilization of coal ever witnessed, there is given available means of achieving ideal operation. The burning of powdered coal under steam boilers with the positive assurance of obtaining complete combustion, a maximum boiler and furnace efficiency, under ordinary conditions of operation and with a smaller number of operators, is an accomplished fact. The inherent disadvantages of the older methods of firing the pulverized fuel have been overcome by the perfection of the carburization process and the Pruden carburetor.

It is claimed that the personal equation existing under conditions of grate-fired practice are eliminated if the installation has been made with due regard to the engineering requirements of the individual plants. The accurate control of air and powdered coal is obtained through suitable valve mechanisms which anyone can intelligently operate. The mixing of the coal dust and the proper amount of air is intimate and complete. Combustion, in the case of any grade or type of coal, even with 20 or 30 per cent. ash, occurs under the most favorable conditions. Every available B.t.u. in the fuel, whether Illinois screenings or North Dakota lignite, is liberated at the earliest possible moment, with the least amount of air necessary for complete combustion, causing a high furnace temperature and a minimum loss of sensible heat in the waste-flue gases.

The old bugbear of slag formation with powdered fuel has beat a hasty retreat under the pressure of actual results obtained under operating conditions where the carburization process is used.



PULVERIZED FUEL INSTALLATION.

The ash, which collects in the flues or on the water-tubes is light, porous and unfused, showing no tendency to form a hard cake, and should give no more trouble in a properly-installed equipment than does soot in ordinary grate-fired practice. The removal of the molten slag and ash from the bottom of the fire-box becomes with practice a simple operation, and, compared with the usual difficulties with clinkers on mechanical stokers, is indeed an item which should cause no real concern.

In case it is necessary to "bank" the fires it can be accomplished by turning a valve. When it is necessary to meet a "peak" load condition the desired boiler capacity is obtained in as simple a manner. When it is necessary to shut down the boiler—to clean out the flues or for other purposes—this can be done instantly, and when desired the fire can be turned on again like gas.

The photograph shows a 150 horsepower horizontal return tubular boiler, fired by two 12-inch Pruden carburetors. The results of an evaporation and efficiency test on the 150 horsepower horizontal tubular boiler fired by two 12-inch Pruden carburetors are of interest. The duration of this test was 23¼ hours. It was witnessed by a number of local engineers and technical men. The coal burned was a high ash (22.09 per cent.), LaSalle County, Illinois, screenings, with a heating value of 10,158 B.t.u. on a dry basis. The coal was dried and pulverized, the coal preparation unit having a capacity of 30 tons of pulverized fuel per day. As burned under the boiler, the coal dust had a moisture content of 2.94 per cent. A screening test showed that 98.8 per cent. passed through a 100-mesh screen and 90.5 per cent. through a 200-mesh screen.

The proximate and ultimate analysis of the coal is given in Table 1.

Table 1

Proximate Analysis

	Dry per cent.	As burned per cent.
Moisture		2.94
Volatile matter	37.61	36.49
Fixed carbon	36.51	35.42
Sulphur	3.79	3.71
Ash	22.09	21.44
	100.0	100.00

Ultimate Analysis

	Dry per cent.
Carbon	60.86
Hydrogen	4.32
Nitrogen	0.99
Oxygen	7.95
Sulphur	3.79
Ash	22.09
	100.00

The results and data of the test are of interest.

Table Data and Results of Evaporation Test

Test of Brownell tubular boiler located at plant at Chicago to determine evaporation.

Kind of furnace: special construction.

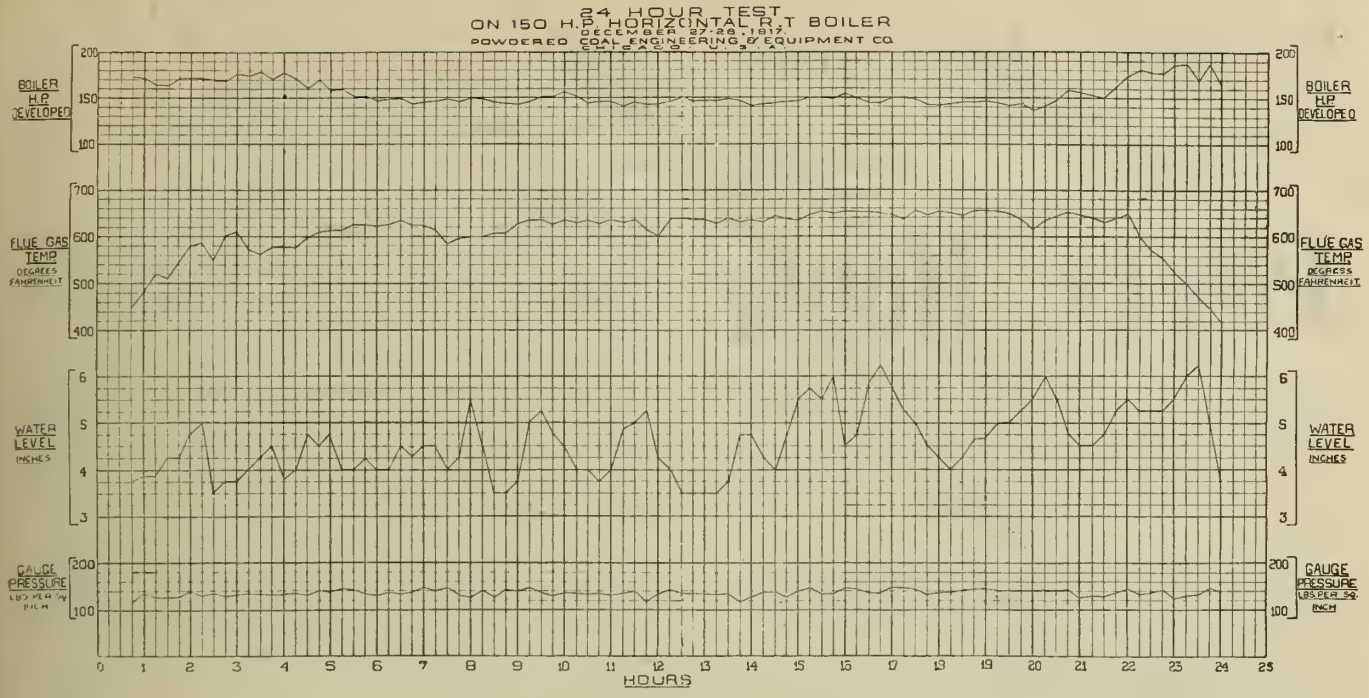
Grate surface: Grate absent; fired by two Pruden carburetors, 12 inch.

Water heating surface—1,504 sq. ft.

Superheating surface—None.

Date—December 27-28, 1917.

Duration—23¼ hours.



24 HOUR TEST
ON 150 H.P. HORIZONTAL R.T. BOILER
DECEMBER 27-28, 1917
POWDERED COAL ENGINEERING & EQUIPMENT CO.
BOILER H.P. DEVELOPED
FLUE GAS TEMP DEGREES FAHRENHEIT
WATER LEVEL INCHES
GAUGE PRESSURE LBS PER SQ. INCH
HOURS

RESULTS OF TEST RUN.

Kind and size of coal—LaSalle County, Illinois, screenings, pulverized 90.5 per cent. through 200-mesh; 98.8 per cent. through 100-mesh.

Average Pressures, Temperatures, etc.

Steam pressure by gauge—One boiler, 145 deg. Fahr.

Temperature of feed water entering—35.1 pounds.

Temperature of escaping gases leaving boiler—609.8 deg. Fahr.

Force of draft in firebox—0.15 in.

Percentage of moisture in steam—0.95 per cent.

Total Quantities

Weight of coal as fired—17.625 pounds.

Percentage of moisture in coal—2.94 per cent.

Total weight of dry coal consumed—17,107 pounds.

Total ash and refuse—3,679 pounds.

Percentage of ash and refuse in dry coal—22.099 per cent.

Total weight of water fed to the boiler—117,835 pounds.

Total water evaporated, corrected for moisture in steam—116,715 pounds.

Total equivalent evaporation from and at 121 deg.—129,554 pounds.

Hourly Quantities and Rates

Dry coal consumed per hour—735.7 pounds.

Water evaporated per hour corrected for quality of steam—5,020 pounds per hour.

Equivalent evaporation per hour from and at 212 deg. Fahr.—5,572 pounds per hour.

Equivalent evaporation per hour from and at 212 deg. Fahr. per sq. ft. of water-heating surface.

Capacity

Evaporation per hour from and at 212 deg. Fahr.—5,572 pounds.

Boiler horsepower developed—162 h.p.

Rated capacity in evaporation from and at 212 deg. Fahr. per hour—5,175 pounds.

Percentage of rated capacity—150 h.p.

Rated boiler horsepower, developed—108 per cent.

Economy Results

Water fed per pound of coal fired—6.69 pounds.

Water evaporated per pound of dry coal—6.84 pounds.

Equivalent evaporation from and at 212 deg. Fahr. per pound of dry coal—7.59 pounds.

Equivalent evaporation from and at 212 deg. Fahr. per pound of combustible—9.73 pounds.

Efficiency

Calorific value of one pound of dry coal—10,158.

Calorific value of one pound of combustible—13,039.

Efficiency of boiler, furnace and grate—72.5 per cent.

Efficiency of boiler and furnace—72.5 per cent.

Cost of Evaporation

Cost of coal per ton of 2,240 pounds delivered in boiler room (including drying and pulverizing)—$4.28.

Cost of coal required for evaporating 1,000 pounds of water from and at 212 degrees Fahr., $0.2793.

The CO_2 content is much higher than average or usual standard practice. It is certain that such a chart has never before been obtained in any type of steam boiler practice over such a long period of time, under operating conditions which are normal and which can be duplicated by ordinary labor any day of the year. The conditions under which the test was made were unfavorable from the standpoint of thermal efficiency, making it appear probable that under continuous service in ordinary weather the high boiler and furnace efficiency, 72.5 per cent. might easily be exceeded. The powdered coal was lighted under a cold boiler three hours before the test was started, the average temperature of the air fed with the powdered coal being approximately 4 deg. Fahr.

Bituminous coal of 18 per cent. ash, under ordinary conditions of grate firing will usually be found to produce an ash which contains from 16 to 18 per cent. combustible. The ash and slag produced in the test given above contained only a trace of combustible, less than 0.1 per cent. It is evident, then, simply from a consideration of the unavoidable losses in grate-fired practice, due to unburned material, that the burning of powdered coal by the carburization process represents a saving in this instance of $0.17 \times 0.22 \times 10{,}158 = 380$ B.t.u. per pound of coal, or a saving of 3.74 per cent. of the heating value of the coal, due only to the fact that the coal is completely burned.

The average modern plant using the same grade of coal would not, under ordinary operating conditions, realize a boiler and furnace efficiency of more than from fifty-five to sixty per cent., as against the efficiency of 72.5 per cent., which was obtained with powdered coal. Take a large central power plant that consumes 6,000 tons of coal per day. Assigning to such a plant an average monthly efficiency of 60 per cent., it is evident that by the installation of the properly-designed powdered coal equipment this company could realize a saving of 12.5 per cent. or 6,000 tons, or 750 tons of coal per day, which, at $5 per ton, would mean a daily saving of $3,750.

Graded Certificates For Ontario Engineers

BEGINNING with the New Year the stationary engineer will be on the same footing as are his brothers in other provinces, so far as certificates of competency are concerned. An act making provision for the grading of certificates was passed by the legislature last spring and regulations have recently been issued by the Lieutenant-Governor-in-Council which make provision for its carrying out.

Four grades of certificates are provided for, and both engineers and firemen must hold certificates of some grade. Engineers in charge of a plant will have to hold certificates corresponding to the grade of the plant under their care, while firemen are required to have at least fourth-class certificates. Exceptions are made in the case of a fireman working for less than six months, and in the case of engineers operating plants under their care when the act goes into effect.

Present holders of certificates will be graded into two classes, second and third, the standing to be determined by the board. The first-class certificates will be granted only upon examination. It will not be necessary for engineers at present operating a plant to obtain the certificate necessary for its operation under the regulations, so long as he remains in his present position, but if he changes to a plant having a higher rating, it will be necessary for him to have the proper certificate for its operation, time being given for his preparation for examination.

The four grades of certificates which will be issued permit of the operation of plants having certain boiler horsepower ratings by the holders of corresponding certificates. This necessitates the grading of plants, and provision is made in the regulations for this being done. Certificates of rating will be issued to power plant owners and these will be placed adjacent to the certificates of the operating engineers.

In general, both the act and its accompanying regulations show evidence of careful working out, and make provision for wise regulation of stationary engineering in Ontario.

Requirements for admission into the various grades are quite severe, and are, in general, higher than those required by other provinces.

The fees are also higher than those for similar grades in other provinces, the fee for examination in the lowest grade being five dollars.

German Uses For Aluminum

THE shortage of copper in Germany during the war drove the Boche engineers to many expedients for the eking out of their supply and for the substituting of other metals to make up the shortage. Aluminum was largely used and of this metal, Germany, thanks to the bauxite deposits of Austria-Hungary, had an abundant supply. Electrical apparatus, generators and transformers were constructed with aluminum to replace the copper and excellent results were secured. Soldered joints were avoided and connections made by screwing and welding. With threaded joints of aluminum the contact surface was made 30 to 50 per cent. larger than with copper to avoid loss of efficiency. Copper plating was successfully practised and the increase in contact resistance due to heating thus avoided.

Generators and motors were constructed with aluminum and at the present time A. C. motors are being built which contain neither copper nor tin. The windings are of aluminum, the connections are sweated, slip rings, cables and brushes are of iron and the bearings are of lead magnesium alloy. Switch-gear, such as knife switches, oil switch contacts, etc., must be made of copper, however, as bad contacts and high contact resistance is apt to occur when the aluminum becomes oxidized with time.

On Regulatin' Prices

IT is a joyful thing, for sure, to read in these here times of how they're treatin' profiteers to jail terms and to fines, and makin' them loose up a spell and drop their ponderous wad, and get right out to earn their bread by gougin' up the sod.

With pure delight I scan them things, I read 'em line on line, while chills of pleasure and of joy they camp upon my spine.

Ah, well, it's time some move was made to shove us folks ahead, and push away the clouds that hang and bump upon our head; it's time they made our dollar sprout like some sweet-smelling vine, for it has shrunk to most like two nickels and a dime.

I wish them men would give to me a seat upon the board that's goin' to boot the prices down and scatter out the horde. I'd like to hear 'em call me out: "Old top, come have a seat, and use your brain to regulate the price of hay and meat."

I'd wiggle my big ears, I would, and hear the widder's cry about the price of liver a-campin' far too high, and then I'd set at once to work upon my new board seat to see that folks like me and you could get enough to eat.

I'd say to them what carve the cows, the rooster and the swine, that pounds of pork chops hence shall sell for just one single dime. A luscious T-bone steak I'd mark with paint and letters bold, and tell 'em that for fifteen cents that there thing should be sold.

I'd go unto the grocery store and say: "You grocery man, just yank the prices you've stuck upon each prune and fig and can, and take 'em quick from out of here; forget your glorious days, and I shall teach you, yes, by gum, to walk in humble ways."

I'd take the hands of time quite rough and wind 'em back a spell before I'd give them grocery men the high sign for to sell. The good old days, the grand old days I'd bring back with a bound, when butter dished up in a boat at 20 cents a pound.

I'd travel up and down the street, I'd visit every place, and buyers would be cheerin' me, a smile hung on their face.

And for my friends what like to smoke I'd surely do a turn, rememberin' cabbage leaves and truck and all things that would burn. The cheers would rise up like a cloud, they'd come from near and far, as I led back to life once more a good five-cent cigar.—ARK.

A Source of Waste

AN unusual case of water waste, described in "Canadian Engineering," was brought to light some years ago in a large office building, where an apparently excessive consumption caused the water officials to attach a meter to the service taps for the purpose of arriving at a suitable charge. It was hardly to be believed, but the registration by the meter showed that more water was being consumed at night, when the building was empty save for the janitor and family, than during the day, with all the offices occupied and water being freely used by all. A careful investigation was made, and it was found that all the toilets were fitted with a very poorly constructed ball cock fixture, which became disarranged every night by the increased pressure in the mains. This allowed a steady flow from the tanks down the waste pipes that lasted throughout the entire night all over the building until the day usage again reduced the pressure. Naturally, the owners of the building had a heavy water bill, but, needless to say, the wasteful fixtures were speedily replaced by others of a better kind, and this unusual and costly source of waste was closed.

The Engineer's Pants

By JAMES E. NOBLE, Again

SEPTEMBER 20 POWER HOUSE, has been received by me, and I have read the skit by ARK on page 423. He seems to love the engineer who waves a pants' worn seat; in fact, he states that such a man is pretty hard to beat.

The man who oozes oil from his boots and other parts is just a pure invention of that clever Mister Ark's. Perhaps the writer of the skit has got that basement sheen. Just let him take his last POWER HOUSE and look at 413. I feel quite sure that Writer Ark will feel so small and queer when he digests that poem by another engineer. There's nothing queer that engineers should sometimes takes a seat when they desire to think a thunk, or swallow up an eat. Most engineers, while standing up, can think as well as eat; their brains are in the upper part, not 'way down in their feet. The skilful touch's a goodly thing, I willingly declare, but such a touch is not much use when bunched up in a chair. It would be hard to move the engines into such a touch. In fact, I feel that such a move would get the chief in "dutch."

Now, I am up to "snuff, by gosh," and pretty hard to beat. I wear no patches at my knees and no gloss at the seat.

The reason that there is no gloss upon my breeches fair is just because I always keep a cushion on my chair.

A HELPING HAND

Engineers, firemen and other power plant operators are earnestly requested to take up any matters upon which they desire information with the Editors of POWER HOUSE. This applies particularly, at the present time, to the grading of certificates in Ontario. Any new development of this kind naturally gives rise to a period of uncertainty and information is often desired by those who are most intimately concerned. We are in a very advantageous position for extending a helping hand to those in doubt as to what to do under the new regulations. Questions regarding the Act, its regulations and their interpretation, requirements for the different grades, studies to be undertaken, etc., will be cheerfully answered.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

Readers are invited to send in answers to these problems, as they have been chosen for their interest and application to the practical side of power plant operation.

Perhaps you, too, have some pet problems, or hard nuts which you would like to ask your fellow engineers; if so, send them along for the benefit of others.

Answers, together with the original question, will be published in the issues following the appearance of the question.

Questions Answered

Question—80. At what pressure will a safety valve blow off, having a diameter of 4 inches, the weight of the valve and stem is 10 lbs., the lever is 20 lbs., and the ball 120 lbs.? The total length of the lever which is straight, is 44 inches. The weight is 40 inches from the fulcrum, and the distance from the centre line of the valve to the fulcrum is 4 inches.

Answer.—To find the pressure a lever safety valve is set for.

Formula: $(W\ L + w\ l + V\ B) \div A\ D$

Where—

W = Weight of load or weight of lever in pounds,

L = Distance of weight from fulcrum in inches,

w = Weight of lever in pounds,

l = Distance from fulcrum to centre of gravity, of lever in inches,

V = Weight of valve and stem in pounds,

D = Distance from centre line of valve to fulcrum in inches,

A = Area of valve in square inches.

Solution:

$$\frac{120 \times 40 + 20 \times 44/2 + 10 \times 4}{4 \text{ squared} \times .7854 \times 4} =$$

105 pounds.

* * *

Question.—81. With a safety valve having the dimensions given in question one, what weight is necessary to have the valve about to blow off at a steam pressure of 100 lbs. per sq. inch?

Answer.—Use the formula:

$W = [APD - (w\,l + V\,D)] \div L$

Solution—

$[4^2 \times .7854 \times 100 \times 4 - (20 \times 22 + 19 \times 4)] \div 40 = 113.66$ pounds.

The letters in this formula are the same as in No. 80, except P = steam pressure in pounds per square inch.

Question.—82. What is the absolute pressure if the vacuum gauge indicates 19 inches, while the barometer stands at 26 inches?

Answer.—Rule: To find the absolute pressure shown by a vacuum gauge, substract the vacuum gauge reading of the barometer and multiply the difference by .49.

Solution—

$(26 - 19) \times .49 = 3.43$ pounds.

* * *

Question.—83. Find the quantity of air required to completely burn one pound of fuel of the following composition: Carbon, 84 parts; hydrogen, 5 parts; oxygen, 7 parts; ash, 4 parts.

Answer.—Rule: To find the air required to burn a given fuel: To the carbon contained in the fuel add three times the hydrogen, multiply the sum by 1.52, and the result will be the air in cubic feet required, at a temperature of 62 degrees Fahr.

Solution—

$1.52 \times (84 + 3 \times 5) = 150.48$ cu. ft.

* * *

Question.—84. How many B.t.u. will be produced by the combustion of one pound of coal of the following composition: Carbon, 76.5 parts; hydrogen, 4.4 parts; oxygen, 3.0 parts; nitdogen, 1.1 parts; ash, 15.0 parts.

Answer—Rule: To find the heat of combustion of one pound of fuel, multiply the percentage of carbon by 146 and the percentage of hydrogen by 620; add the products and the sum will be the required heat of combustion in B.T.U.

Solution—$.146 \times 76.5 + 620 \times 4.4 =$ 13,897 B.T.U.

* * *

Question.—85. How many pounds of water at 212 degrees Fah. can be evaporated by 1 pound of the coal mentioned in question 5?

Answer.—Rule.—The find the number of lbs. of water at 212 degrees Fah. evaporated by one lb. of fuel. Divide the heat of combustion by 966.

Solution.—The heat of combustion was found to be 13,897 B.T.U. Therefore, 13897 divided by 966 = 14.38 lbs.

* * *

Question.—86. A boiler shell 72 inches in diameter is constructed of material 5 inches thick, which has a tensile strength of 60,000 lbs. per sq. in. What is the bursting pressure, taking no account of the weakening effect of the seam?

Answer.—Formula: $P = ts \times t \div d$.

Where ts = tensile strength in pounds per sq. inch.

T = two thicknesses of plates in inches.

D = diameter of boiler in inches.

P = bursting pressure in pounds per sq. inch.

Solution.—$60{,}000 \times .5 \times 2 \div 22 = 833.33$ lbs. per sq. in.

* * *

Question.—87. If the boiler shell whose dimensions are given in question 86 is constructed with a triple-riveted, double-strapped belt joint having an efficiency of 86 per cent., what is the bursting pressure?

Answer.—Multiply the bursting pressure in the former example by the efficiency of the joint in this question, the result will be the answer.

Solution.—$833.33 \times .86 = 716.66$ pounds per sq. in.

* * *

Question.—88. Find the load on a stay when the pitch is 8 inches either way and the steam pressure 83 lbs. per sq. inch.

Answer.—To find the load on a stay, multiply the area supported by it, by the working steam pressure in lbs. per sq. in.

Solution.—$82 \times 83 = 5{,}312$ lbs.

* * *

Question.—89. Staybolts 1¼ inches in diameter are placed 3½ inches from centre to centre. If the steam pressure is 100 lbs. per sq. inch, what is the stress per sq. inch in the stays?

Answer.—Rule.—The stress per sq. in. on a stay is found by multiplying the area in sq. in. supported by the stay by the working steam pressure in pounds per sq. in., and divide the product by the least cross sectional area of the stay in sq. ins. There, the area of the staybolt is $1¼ \times .7854 = 1.2272$.

The stress is, therefore, $8½^2 \times 100 \div 1.2272 = 5{,}867.39$ lbs.

* * *

Question.—90. A stayrod 2 inches in diameter is cut with a U. S. standard thread and has 4½ threads per inch. What is the diameter at the root of the thread?

Answer.—Rule.—To find the diameter at the root of the thread, divide 1 by number of threads to the inch = 1 divided by 4½ = .2222 inches. This gives you the pitch of the thread. Then to find the depth of the thread multiply the pitch by .6495. Now we have $.2222 \times .6495 = .1443$ inches (depth). Then to find the diameter at the root of the thread. $D = 2 - 2 \times .1443 = 1.7114$ inches.

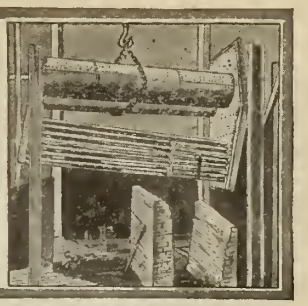
NEW POWER PLANT EQUIPMENT



SAFETY ENCLOSING COVER FOR MOTOR CONTROLING RHEOSTATS

As a result of almost continual widespread "Safety-First" campaigns, the necessity for safeguarding all machinery and those who operate it, is now generally recognized throughout the realm of industry as a matter of vast importance. In the electrical field rapid progress has been made in the past few years in designing new lines of apparatus redesigning old ones to make the safety feature more prominent, and particular attention has been paid to motor control device because, as a rule, this class of apparatus is handled either by unskilled labor or by those not familiar with electrical machinery, and the necessity for a fool-proof installation is the more obvious.

It is interesting to note how the face-plate rheostats manufactured by the Westinghouse Electric and Manufacturing Company, shown in Fig. 1, are protected, and how the enclosing covers are so designed that they can readily be applied to old rheostats to make old installations strictly modern.

As shown in the accompanying illustrations the enclosing cover is a solid sheet steel box which fits tightly against the rheostat base and is secured by four corner bolts. Pivoted to the cover are two cast iron arms, one with the operating handle on the outside, and one within made with a fork to engage the rheostat handle. To apply a safety cover to an old rheostat, it is only necessary to remove the four nuts on the corner studs of the face-plate and place them with adapter nuts and studs, furnished with the cover. The rheostat handle is

RHEOSTAT READY TO ATTACH COVER SHOWING ADAPTERS REPLACING NUTS AND FIBRE TUBE REPLACING HANDLE.

also removed and a fiber tube substituted. The cover is then put on so that the fork on the inner arm engages the insulating tube and the four nuts that were on the original rheostat are used to fasten the cover in place. The lead wires from the rheostat are brought through insulating bushings that are held in place by the edge of the cover. While no packing is used to make the cover water-tight, it fits so closely that it effectually prevents the entrance of metal chips, sawdust, or other material that would cause injury to the rheostat. The cover is grounded through the corner bolts, and being insulated from live

RHEOSTAT WITH SAFETY ENCLOSING COVER IN PLACE.

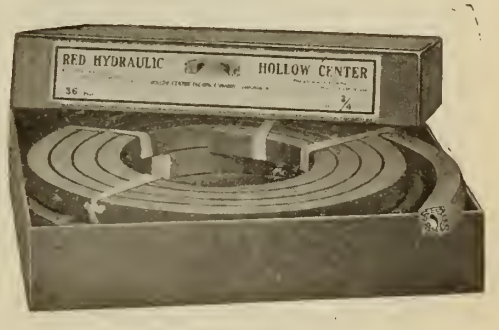
parts, renders it fool-proof and makes it impossible for an operator to accidentally receive a shock through coming in contact with the working parts of the face-plate.

The use of these covers or similar devices is one of the important requirements of the modern factory or machine shop, and in some localities it is demanded by law. These covers fulfill all requirements of a safety-first device and are easily and readily installed.

OVALHOLE PACKING

A new packing has been developed for the circumventing of the many piston packing troubles common to the engine room. It is often a difficult matter to keep steam from blowing past the packing in cases where rods are worn out of round. To obviate this difficulty, the Hollow Center Packing Co., Cleveland, developed the packing shown in the accompanying illustration.

The hole is oval shaped so that the packing is flexible and when put under strain by tightening the gland, it readily expands to compensate for irregularities. Another feature, it is pointed out, is the fact that the hollow construction gives the packing comparatively long life, due



OVAL HOLE HYDRAULIC PACKING.

to the fact that as the action of the rod wears the packing away, setting up the gland elongates the packing rings, making them fill the gland completely. It is said that the hollow design also eliminates undue friction which is apt to score the rod.

This material is made in three different grades; one for ordinary use, with steam at pressures up to 125 pounds, one for inside packed pumps and hydraulic service, and another high-pressure superheated steam. This latter is constructed of the highest grade heat-resisting material impregnated with a springy heat-resisting rubber compound

OVALHOLE REGULAR PACKING.

HIGH PRESSURE STEAM PACKING.

vulcanized to withstand high temperatures.

THE AUTOMATIC SUB-STATION FROM AN ECONOMIC STANDPOINT

The tendency in the development of modern electrical apparatus is to utilize more and more the automatic features which are proving to be important factors in extending its use.

No recent development has created more general interest of possesses more economic possibilities than that of the automatic sub-station.

The automatic sub-station in simple language consists of a synchronous converter, a bank of transformers and three mounted electrically operated switches, relays and instruments. It is really uncanny in what it will do when trolley voltage falls below a predetermined safe value, without human aid the converter starts up and reaches synchronism and assumes its share of the total load on the line. If the load increases to a point dangerous to the converter it immediately shuts itself down and the line switches all open. If a converter bearing should overheat, instantly a relay operates and the converter shuts itself down. If the load on the line drops to a point where the converter is not required, it automatically comes to rest. It will go through this cycle of starting and stopping just as often as the line conditions make it necessary, it being possible to start up, close all switches, open all switches and stop the converter twice per minute.

Naturally, since such power is at instant call without an attendant at the station certain limitations exist which react to counterbalance the good qualities of automatic switching, but they in no way destroy the great economical advantages of such switching.

A competent engineer must inspect the apparatus weekly, and the station must be cleaned up three or four times a month. One engineer could inspect a great many stations on a regular schedule so this item will add but a trifling labor charge. The cleaning up can be done by ordinary car barn labor.

The original investment, will, of course, be greater than a manually operated station of equal capacity.

There may be increased hazard to the equipment, although results thus far obtained, indicate that the equipment is better protected by automatic switching than by hand switching.

The automatic switching is more complicated than hand switching, but on close acquaintance it becomes quite simple.

Feeders must be applied with great care to save trolley wires which drop to the ground from annealing.

Since there are no operators to transfer high tension lines in case of trouble, these lines may in certain cases, have to be arranged for automatic installations. It may be possible to handle this high tension switching by remote control.

The economic features which offset the foregoing disadvantages are so great that they leave a heavy balance in favor of the automatic switching.

The fact that automatic sub-stations require no attendants should itself effect an economy of $2500 per station allowing two men per station for hand switching.

The absence of attendants leads directly to a second marked advantage, the elimination of labor difficulties. This is an important factor under the present disturbed condition of labor generally.

By re-locating or increasing the number of sub-stations enough feeder copper can be saved on many propositions to pay for a great proportion of the cost of automatic switching.

There is invariably a reduction of electrolysis due to absolutely correct location of automatic stations, thus reducing the return circuit in length and in losses due to drop.

Experience thus far indicates that reliability of operation will be increased. Considering the ability of the best operators than can be secured and the introduction of the ever varying "human element," the automatic switching should prove by far the more reliable method of operation.

Maintenance has been very low in those cases which have been under operation.

This charge will drop exactly in the proportion that inspection and cleaning of apparatus is kept up, and with experience, will doubtless drop to a very low value.

Summing up, there is no doubt but what the automatic substation is here to stay and its economic features demand consideration whenever the installation of a new sub-station is projected.

OUR QUESTION BOX

Continued from page 450

Question.—91. What working pressure will be allowed on a solid rectangular steel girder 2.5 ft. long, 7 inches deep and 2 inches thick, fitted with three staybolts? The girders are spaced 7 inches centre to centre. The pitch of the stay-bolts is 7.5 inches and the combustion chamber is 30 inches wide.

Answer.—The formula for this problem is as follows:

$B = Cd^2 T \div (W-P) DL.$

Where:

B = pressure in pounds per sq. inch

D = depth of girder in sq. inches.

T = thickness of girder inches.

W = width of combustion box, in inches, measured in the direction in which the girder is applied.

P = pitch of stay-bolts, in inches.

D = distance from centre to centre of gorders in inches.

L = length of girder in feet.

C = girder fitted with two or three stay-bolts, 825 is the constant for this

Applying the formula: $825 \times 7^2 \div (30-7.5) \times 7 \times 2.5 = 205.3$ lbs. p sq. in.

Question.—92. A boiler shell 60 inches in diameter and ½ inch thick, with a tensile strength of 60,000 lbs. per sq. in., has a double riveted longitudinal lap joint, having a rivet efficiency of 68.3%. Under Canadian Marine Rules, what working pressure will be allowed? All rivet holes are punched before bending.

Answer.—The factor of safety for the rivets in Canada is 4.25. For the shell this factor is increased by .5 and by .2, because all rivet holes are punched before bending, and also by .2 because double-riveted longitudinal lap joints were used, thus making the shell factor of safety $4.25 + .2 + .2 + .5 = 5.15$. Then the working pressure on the rivets is: $60{,}000 \times .683 \times ½ \times 2 \div 60 \times 4.25 = 160.71$ lbs. per sq. inch. Working pressure on plate is: $60{,}000 \times .743 \times ½ \times 2 = 144.27$ lbs. per sq. inch. The lowest pressure found by this calculation is taken as the allowable working pressure.

Therefore, 144.27 lbs. per sq. inch will be right.

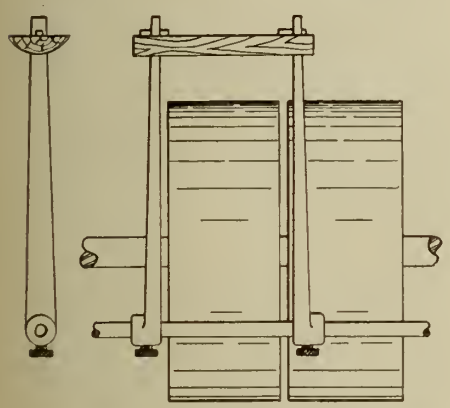
The Operators' Point of View

METHOD OF KEEPING THE BELT IN THE SHIFTER FORKS

By L. G. Singer

(Copyright. All rights reserved)

Frequently when a belt is shifted suddenly it flops out of its proper position between the shifter forks. This also may happen when the belt is loose



KEEPING THE BELT IN SHIFTER FORKS

or the shifter forks are too short. Such occurrences can be prevented by fixing (after the belt is in position) a wood strip across the lower ends of the forks, as shown in the accompanying picture. The strip can be held in place with spring cotters, set in drilled holes as suggested, or with pieces of wire suitably bent.

WATER GAUGES AND GAUGE GLASSES

On page 292, July 5, POWER HOUSE, R. Manly Orr describes a method for improving the water gauge. We all know how easily a gauge glass will break if it receives the slightest of scratches. Pulling the light spring off and forcing it on, and allowing the steel rod to lie against the glass makes three chances for such a scratch. It is good engineering to keep all metal contacts away from water glasses in use on high pressure boilers. The snaps could be arranged so that they would go over the gauge, fitting with the rod slightly away from the glass. A small or narrow strip of cardboard, bright red, green or other clear color, placed behind the glass and fastened at the top and bottom with a bit of string will answer the same purpose. The water acts as a magnifier and the height of the water is shown by the color all across, or filling the glass, above the water level only the narrow strip of color shows.

Gauge glasses with colors run into the glass, usually bright red, are made and have been on sale for many years.

Jack McAndrew.

COLORING LAMPS

On page 291, July 5, POWER HOUSE, there is an article by J. C. Supton on coloring incandescent lamps. Part of which follows, was published some years ago. Take a little white shellac, thin it down with alcohol, and by dipping the bulb in this is produced a splendid imitation of frosted glass when a clear white light is required. Care must be taken to have the shellac fairly thin, so that it will run smooth. If you use green, purple, red, blue or any other colored lamps, buy a package of egg dye of the color required, dissolve it in wood alcohol and pour it into the shellac. By using this or any transparent coloring, a vast number of beautiful tints can be made that will blend with any color scheme.

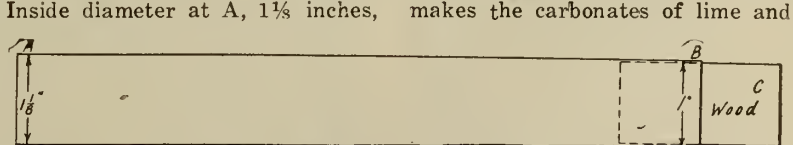
To go about it properly and to get the best results, after preparing your shellac, pour it into a vessel deep enough to immerse the lamp. Take a piece of wire and fasten it around the socket of the lamp, and bring over one end of the wire back over the end of the lamp to opposite side of the lamp to form a loop, then dip it in the solution and hang it up to drip and dry. (I have found by experiment that as good or better a coating can be given a cold lamp than a warm one, the coating being absolutely uniform with no streaks.)

While mixing in your color, bear in mind that the more dye and the less shellac the deeper the tint will be, and vice versa. Any of these colors can be removed with wood alcohol. Water has no effect on them.—J. E. M.

COMMUTATOR DRESSING

From a piece of galvanized sheet iron, tin or copper, make a tube 12 inches long. Inside diameter at A, 1⅛ inches, at end B, 1 inch only. This is the mould.

Have a piece of round wood 3 or 4 inches long, which will be a snug fit into end B.



COMMUTATOR DRESSING

Melt one pound of paraffine wax and add half a pound of bi-carbonate (baking) soda, and half pound fine powdered graphite, stir all well together and fill the mould. The wax must be very hot when the soda and graphite is added.

When the mixture is cold, hit the wood block at C a sharp blow with a hammer and this will drive the compound stick forward so that it can be drawn from the mould.

Save the tinfoil removed from friction tape and wrap is around the sticks to keep them clean, etc. The sticks should be cut into 5 or 6 inch lengths as they are about right for handling in this length. A little of this compound used on commutators once in a while is much better than dosing them with vaseline or dynamo oil as is frequently done.

FEED WATER HEATERS

By R. MacLaren

In a plant with which I am acquainted there is a closed feed water that is too small for the job as the feed water temperature is around 150 deg. Fahr. Later in the season when the lake temperature is higher it will rise to over 160 deg.

The heater is of the water-tube type, that is, the water circulates through tubes with the steam on the outside, and as the water enters at the upper end of the tubes and leaves at the lower end impurities get no chance to lodge in them.

While a closed heater of sufficient capacity will undoubtedly heat the water to over 200 deg., I believe that the open heater has merits which make its selection the only reasonable one in this particular case.

To raise the temperature to over 200 deg. a closed heater must have proportions more liberal than most builders are willing to give them, and certainly more liberal than most plant owners are willing to pay for.

When water containing bi-carbonates of lime and magnesia is heated to 180 to 212 deg., the carbonic acid gas which makes the carbonates of lime and magnesia soluble in water is driven out of combination with the carbonates and the latter are precipitated.

Given a chance, the CO_2, which is cor-

rosive, will leave the water, as will also the carbonates. In the closed heater there is no such chance, everything being swept on into the boiler. In the open heater, any good type of which has a filter incorporated in it, the gas has a chance to escape and the carbonates are caught in the filter.

In the open heater, the steam and water being in direct contact, if there is the quantity of exhaust steam present in the heater, theoretically required to heat the water, the water will be raised to a temperature of 212 deg. or higher, depending on the pressure.

The open heater is also a water saver. To heat the water from 50 to 212 deg equals 162 deg. rise, one pound of steam will heat $\frac{966}{162}$ equals 6 pounds almost of water; 6 pounds of water and 1 pound of steam equals 7 pounds feed water. That is, the open heater saves one-seventh of the feed water.

If there is a battery of four boilers of 130 h.p. each, and they are working up to their rating, they will use 15,600 pounds of water per hour. One-seventh of this equals 2,230 pounds, equals 223 gallons per hour.

The open heater also saves boiler compound. In the case of the closed heater in question, the compound has to deal with the carbonates as well as the sulphates. The open heater takes care of the carbonates and the compound has only the sulphates to deal with, and ought to be applied to the water after it has passed the heater.

MORE POWER PLANT AND OTHER KINKS

By J. E. McCormack

About 1½ years ago I clipped from a newspaper a recipe for making waterproof ink for use in labelling. I tried it and think it worth passing on as it is good and also inexpensive. Here it is: "In a small bottle place an ounce and a quarter of methylated alcohol, add a half ounce of shellac, and when this last is dissolved, immerse the bottle in hot water until the solution is warm. Then add slowly, while stirring rapidly, a solution composed of one hundred and fifty grains of borax dissolved in two ounces of water. Finally add coloring matter to suit, 4 or 5 grains of methyl violet being satisfactory, and dissolving well upon shaking. This makes a very fine waterproof ink for writing the labels on botles and for other purposes."

In making it I had some difficulty in getting the given amounts of alcohol and of water to dissolve the shellac and borax, in fact, I finally added just a little bit more to make the last few grains dissolve, but when finished I liked the ink. I tried to get it dense enough by adding black dye, to make a drawing ink, but did not get it to give good blue prints, so abandoned this phase of the subject. Later I tried some by adding a little water and as much yellow dye as the mixture would dissolve. This was more successful, but I prefer the purchased liquid waterproof India ink for drawing.

The tightener on a twelve-inch belt was so heavy that it was customary to use two men to lift it. Later, when running short-handed, it was not always convenient to procure a helper from another machine and I found that by standing on the lower part of the belt, about six inches from the floor, and putting my shoulder under the upper part of the belt, I could raise the tightener without help and set a prop under it, whereas I could not in other positions secure such an hold and footing as would enable me to raise the tightener alone. By forcing the belt apart, as above described, after having put my weight on the under half to tighten it, I could apparently use my strength to better advantage.

* * *

After fitting some machinery together in which we used such bolts as were at hand, we had quite a few bolt ends protruding ¼ to ¾ of an inch, and we wished to cut them off. The other fellow said wait until to-morrow. When to-morrow came he appeared on the scene carrying a big cold chisel, perhaps 1¾ inches wide or more and weighing probably eight pounds. His method was for him to hold his big cold chisel tight against one side of the bolt to be cut, while I with an ordinary sized cold chisel and a hammer attacked the bolt on the other side. I was surprised to find that his chisel cut into the bolt about as far as mine did, each chisel cutting to near the middle of the bolt. Apparently it was like a man putting a hundred lbs. on a small rope, it did not matter if the rope was tied to a post or was being held by another man pulling 100 lbs. on the other end. The strain on the rope is the same. Similarly, with the same blow on my chisel his chisel in bracing against mine did its share of the cutting. We soon had the bolts trimmed.

* * *

When doing repair work where old wooden parts or materials are involved and there is some danger of hitting a nail or nails when boring required new holes, the boring often may be done by means of twist drills. They must occasionally be removed and cleared of chips as the work proceeds. They will bore a little more slowly than the ordinary carpenters' bit will do, but will not be damaged by cutting against a nail. I also find that if one is using a brace which has no ratchet attachment, and he is boring in wood, and in a place where he can only make ½ to ¾ turn of the brace each time, then a twist drill used instead of a carpenters' bit will bore a hole under these circumstances. It would not do, though, to try this latter method when drilling iron, because the backward turning would put a wire edge on the drill, thus interfering with its cutting qualities when turning forward again.

When lacing belts by means of leather laces, the end of the lace may be hardened to facilitate pushing it through the holes by holding it in the flame of a match for a few seconds. A little experience will enable one to get it about right on most laces, but sometimes one gets some from which oil fries out and ignites, and the leather crumbles away when squeezed. With this class the flame is no use. Possibly with some of them hot water, if convenient, will serve as I have known scalding water to harden some grades of leather.

* * *

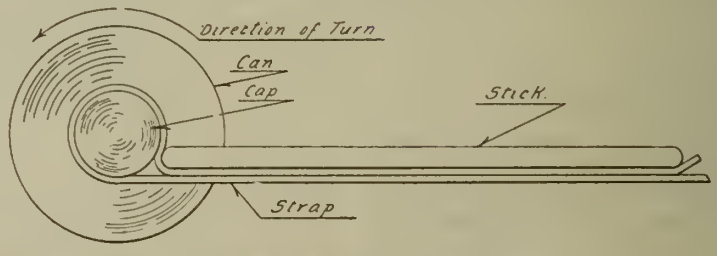
On small engines I have sometimes found an eccentric and crank pin oil cup having an upright tube or spout in its centre. Evidently the idea was to prevent oil flow except during the time the engine was in motion. It was once the custom to use a wick in the tube or spout of all such cups. This wick required attention every few days as it would clog or else would pack and would not let enough oil flow even though at first adjusted for plenty of flow. As an experiment the putting in of a piece of coarse wire or a small iron rod effectively and very satisfactorily replaced by the wick, and by a little experimenting the size and length use could be regulated to suit the oil flow. Shortening it (within limits) to allow it some up and down motion when the engine was in motion increased the amount of flow. By changing both size and length the flow can be widely varied.

METHOD OF REMOVING CAPS OF METAL CANS

By R. W. Stafford

(Copyright. All rights reserved)

When the metal cap of a harness dressing or a metal polish can sticks, it can be readily loosened by gripping it with a loop of leather strap—shawl strap or rein, for example—the hitch being held on the cap with the fingers. If it proves particularly obstinate, a stick of wood can be applied as a lever, as shown in Fig. 1. This method has been found very effective in a number of instances.



REMOVING STUBBORN CAPS

DIRECT USE OF COAL AS FUEL WASTES MANY VALUABLE BY-PRODUCTS

In a monograph on the subject of the "Coal Resources of Canada—Their Relation to the Industrial Development of

the Country," by Mr. F. E. Lucas, published in The Final Report of the Fuel Controller, the advantages of utilizing coal in the production of coke, rather than using coal directly as a fuel, are pointed out. After showing the favorable qualities of coke as a fuel, the paper says:

"In the production of coke many valuable by-products are obtained: gas, tar, ammonia, benzol, toluol, xylol, and naphtha, or combining the latter four, a motor fuel much superior to the best gasoline obtained.

"We are not getting anything like the amount of light, heat, or power we should, or could get, and in getting this extra light, heat and power, we would not only be conserving the coal supply but getting cheaper power and at the same time recovering other products which would be of great economic value to the country and lead to the extension of existing industries and the establishment of new ones.

"Starting with the importation of anthracite, which is practically all used as domestic fuel. This can be almost entirely eliminated, and in so doing give as large returns on the invested capital as any industrial concern in the country.

"Referring back again to the by-products, a word now about their use and the markets available.

Gas

"If the plant is near a large city or thickly-populated district, it might all be sold for domestic lighting and heating. This is done in many districts by selling direct to existing gas companies, for no gas company can produce gas at the price at which a by-product coke plant can afford to sell it. Or if there are large industrial works within reach, it can be sold to them and at such a price as to be more economical than coal, or it can be used in gas engines and power developed. The figure generally accepted as being reasonably conservative for gas-engine practice is 11,500 B.t.u. per horsepower, and it will be readily seen how tremendous quantities of power can be made available from this source.

"Gas supplies for domestic use must have the sulphur extracted. This is done by iron oxide, from which the sulphur can be recovered for the manufacture of sulphuric acid, which is needed for the production of ammonium sulphate.

Tar

"This product can be used directly as a boiler or furnace fuel by being burned in the same manner as oil, or it can very cheaply be dehydrated and the more highly volatile matter extracted and then used for road binding. Even for firing it would be found advantageous to dehydrate. Some tars, depending on the temperature and conditions of the coking process, can be used as fuel for Diesel engines. The most economical way to handle the tar, however, is to distill it and recover the various volatile fractions, such as the benzol, toluol, naphtha, the carbolic oils, creosote, naphthalene, and pitch.

"The benzol, toluol, naphtha, etc., can be added to that recovered directly from the gas, for motor fuel. The crude carbolic finds a market with manufacturers of antiseptics, colors, explosives, and a great deal is used in recent years in the manufacture of phonographic records, imitation amber for pipes, etc.

"So far as the value to the country is concerned, the creosote recovered is one of the most valuable by-products of the coal. Railway ties have doubled in price in the past ten years, and there is every prospect of a pro rata increase in further years. The forestry branch reports 19,100,000 ties used on Canadian roads in one year. A fairly safe assumption would be a complete renewal of all ties every five years, while fifteen years might be taken as a reasonable average life for creosoted ties. The cost of creosoting is less than the cost of a new tie, so that the creosoting of the ties becomes not only a commercially attractive proposition, but will save many millions of feet of lumber annually.

"The same process of reasoning may be applied to mine ties and timbers, and also to bridge timbers.

"The general adoption of the creosoting process would materially reduce this number in a few years. If we assume a consumption of only 10,000,000 ties per annum there would be required about 25,000,000 gallons of creosote oil per year, or the distillation of 85,000,000 gallons of tar, which would in turn require the carbonizing of 8 000,000 tons of coal.

"The naphthalene finds a market as a color base, for the manufacture of deodorizers, disinfectants, moth balls, etc., and also in the manufacture of a chlorinated wax for use in electrical work.

Benzol

"Under this name is often included the toluol, xylol and naphtha, which are recovered at the same time. Each of these products, together with naphthalene, can be recovered separately and refined to their chemically pure state, and there will undoubtedly be a market for a small quantity of each for solvents, dry cleaning dyes, explosives, etc. During the war the toluol and a considerable portion of all benzol recovered was used in the manufacture of explosives.

"The great market now the war is over is undoubtedly to combine the four products, benzol, toluol, xylol and solvent naphtha, as a motor fuel, giving a product which distills between 78 and 165 degrees C. This fuel has been carefully tested and found to give from 20 to 30 per cent, greater mileage than the best gasoline, with about 15 per cent. greater power, easier starting, no knock with advanced spark and actually less tendency for the formation of carbon in engine cylinders. Benzol itself comprises approximately 70 per cent. of the fuel and this freezes at 44 degrees Fah. The addition of the toluol and other products named, in the proportion in which they are recovered, brings the total fuel mixture down to a freezing point of approximately zero F., so that to make an all-year fuel for our climate we have to mix with sufficient gasoline to lower the freezing point still further. The addition of 25 to 30 per cent. of gasoline gives a freezing point low enough for most places, except in the north, where it might be necessary to add as high as 50 per cent.

"According to Government statistics, Canada's consumption of gasolene in 1916 was 74,000,000 gallons, of which 18,000,000 gallons was imported as distilled product, and most of the remainder was made from imported crude oils. So that it is evident that with a total Canadian production of say 20,000,000 tons of coal, if it was all carbonized and the motor fuel recovered, the market would still be far short of being satisfied. This does not take into consideration the fact of the continued yearly increase in consumption which is bound to occur.

Ammonia

"While this has been shown in the balance sheet as sulphate of ammonia which is used almost entirely as a fertilizer, yet it can be recovered in the form of concentrated liquor containing from 16 to 25 per cent. ammonia for the manufacture of explosives, or in the form of dry ammonia gas for refrigerator purposes, or as the aqua ammonia of commerce and chemistry. However, these are only small markets when compared with the market as a fertilizer. Its only competitor, as a nitrogenous fertilizer, is nitrate of soda from Chili, and as the population of the country increases and virgin lands become exhausted, we must, if we are to be fed, keep up the productiveness of the land in a great measure by the use of artificial fertilizers.'

RELATIVE ADVANTAGES OF ROTARY CONVERTERS AND MOTOR-GENERATORS

By C. A. Booth

(Copyright. Al rights reserved)

It is frequently necessary to supply direct current when only alternating-current power is available on the public service company's mains. Either motor generators or rotary converters may be used for converting the direct to alternating-current power. But a rotary converter is probably the most desirable for such service. This statement might not have been true five years ago—before the rotary or synchronous converters were developed to their present state of perfection. The synchronous converter usually costs less and occupies less floor space than does an equivalent motor-generator. However, there is a fixed relation between the alternating-current voltage delivered to a synchronous converter and the direct-current voltage delivered by it. On the other hand, with the motor-generator, either the alternating or the direct-current voltage may, within reasonable limits, be varied independently of one another. The direct-current voltage furnished by a synchronous converter can, however, be, with suitable equipment, increased or decreased by adjusting the alternating-current voltage. One feature of a synchronous motor-generator set which sometimes makes its installation desirable is this: By over-exciting the synchronous motor, the power-factor of the alternating-current system which serves it may be improved.

Trade Gossip

Jenkins Bros., Montreal, have recently obtained a large order for valves from Cuba. It has been learned that considerable business in this connection is developing from South America and the West Indies. Plenty of shipping space is available for export in this direction.

From a statement recently made by an official of the Canadian Pacific Ocean Service, there is every reason to believe that there is plenty of space available for the export of Canadian products. As a matter of fact, many shipping firms are looking for cargoes, and it would appear that the cry of exporters of lack of shipping space, due to the requirements of the Ministry of Shipping, is not warranted.

The Montreal General Tool Company are now manufacturing the "Victory" water heating system, and they have constructed a system at the factory for demonstration purposes. They will carry on this new development in conjunction with their line of Talbot boilers, which are oil-fired. They have already obtained a large contract for installation in a new church to be erected in Notre Dame de Grace. This will be the first installation of its kind in Canada the fuel being crude oil.

The Canadian S K F Company, Ltd., Toronto, have issued Bulletin No. 3 of their series on ball bearing applications. This is the first of several on their application to electric motors.

The Bureau of Mines, in connection with the opening of their new laboratories at Pittsburgh, have issued a very attractive and interesting booklet, descriptive of the various portions of the new development.

The Heine Safety Boiler Co., St. Louis. Mo., have issued an interesting book on "Marine Boiler Logic." This publication is descriptive of the new type of Heine marine water tube boiler and its application to present day shipbuilding requirements.

Mr. L. G. Chase, formerly efficiency engineer, Rosemary Manufacturing Company, Rosemary, N.C., has been appointed mechanical engineer of the Yarnall-Waring Co.

Franklin W. Gilman, combustion engineer with the Sanford Riley Stoker Company of Worcester and the Murphy Iron Works of Detroit, is sailing from Vancouver on October 2 for Japan. He will remain in that country for about a year in connection with the installation and operation of stokers (manufactured by the two companies).

CORRECTION

In one of our last issues we had occasion to review a circular illustrating and describing "Bowser" lubricating oil storage systems. Credit should have been given to the S. F. Bowser Company, Ltd., Toronto, Ont., as manufacturers of the system in question.

VULCAN SOOT CLEANERS FOR RETURN TUBULAR BOILERS

is the title of a new bulletin just published by the Vulcan Soot Cleaner Company, Du Bois, Pa. This bulletin describes their Model "M," front end type, and their Model "R," rear end type. The bulletin states that since 1906 approximately two million h.p. of return tubular and Scotch marine boilers of many different types were equipped with these two cleaners.

The bulletin shows how the cleaner is installed in settings of typical construction. It gives the results of tests conducted by the Engineering Department of the University of Illinois, and by the Iowa Soldiers' Home, at Marshalltown, Iowa.

All engineers who are anxious to save coal, who operate tubular boilers, and who are troubled with soot, should have a copy of this bulletin.

INDUSTRIAL LIBERTY

Industrial liberty, like civil liberty, must rest upon the solid foundation of law. Disregard the law in either, however good your motives, and you have anarchy. The plea of trades unions for immunity, be it from injunction or from liability for damages, is as fallacious as the plea of the lynchers. If lawless methods are pursued by trades unions,

whether it be by violence, or by intimidation, or by the more peaceful infringement of legal rights, that lawlessness must be put down at once and at any cost."

—Louis D. Brandies.

Montreal.—Further developments of the water powers of the St. Maurice River is being considered by the St. Maurice Paper Company. It is understood that the company has leased two sites on the river known as Les Forges and La Gabelle, and it is intended to combine these two, which will give a head of 33 feet, and increase the power now available about 40,000 horsepower.

Extensive preparations are now under way for the Jacques Cartier centennial to be held next month in Montreal. This celebration will last for eight days, from August 9th to the 17th inclusive. An industrial fair will be held in connection with the event and to this end exhibition stalls are now being erected on Fletcher's Field, where the main festivities will take place. It is anticipated that the Prince of Wales will unveil the monument during his visit to the city.

New Quarters.—The International Machinery and Supply Company have acquired a four storey building at 421 St. James Street, Montreal, and in a short time will remove from their present office. The new building will have a floor space of about 7,000 square feet, and in addition to their present activities the firm will start an electrical department. R. J. Hiller will be the manager of the new department.

NON-CORROSIVE
CYLINDER OIL
MANUFACTURED ONLY BY
E. H. KELLOGG & CO.
Nos. 242 & 244 SOUTH ST. NEW YORK, U.S.A.
FRICTION LOSS
An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done — give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

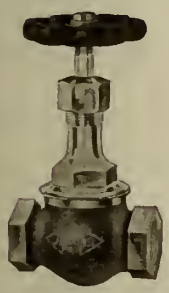
VALVES

TRADE JENKINS MARK



Jenkins Bros

Favoured—and Why!

DEPENDABLE Valve Service at MINIMUM upkeep cost. This is the reason why JENKINS BROS.' VALVES have won the confidence of power house Engineers and Superintendents for over half a century. Extra good quality of metal, careful construction and scientific design (that is they are made extra heavy and strong at points where pressure and strain is greatest) accounts for their superiority.

There's a Jenkins Bros.' Valve for every purpose. You will know the genuine article by the **Diamond Trade Mark** with the signature **Jenkins Bros.** cast on the body. Never fail to look for it. It means service and **economy** to you.

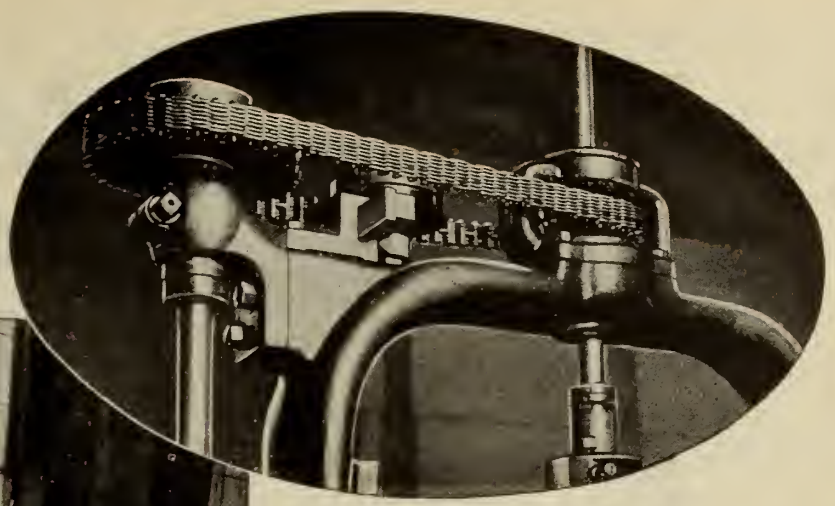
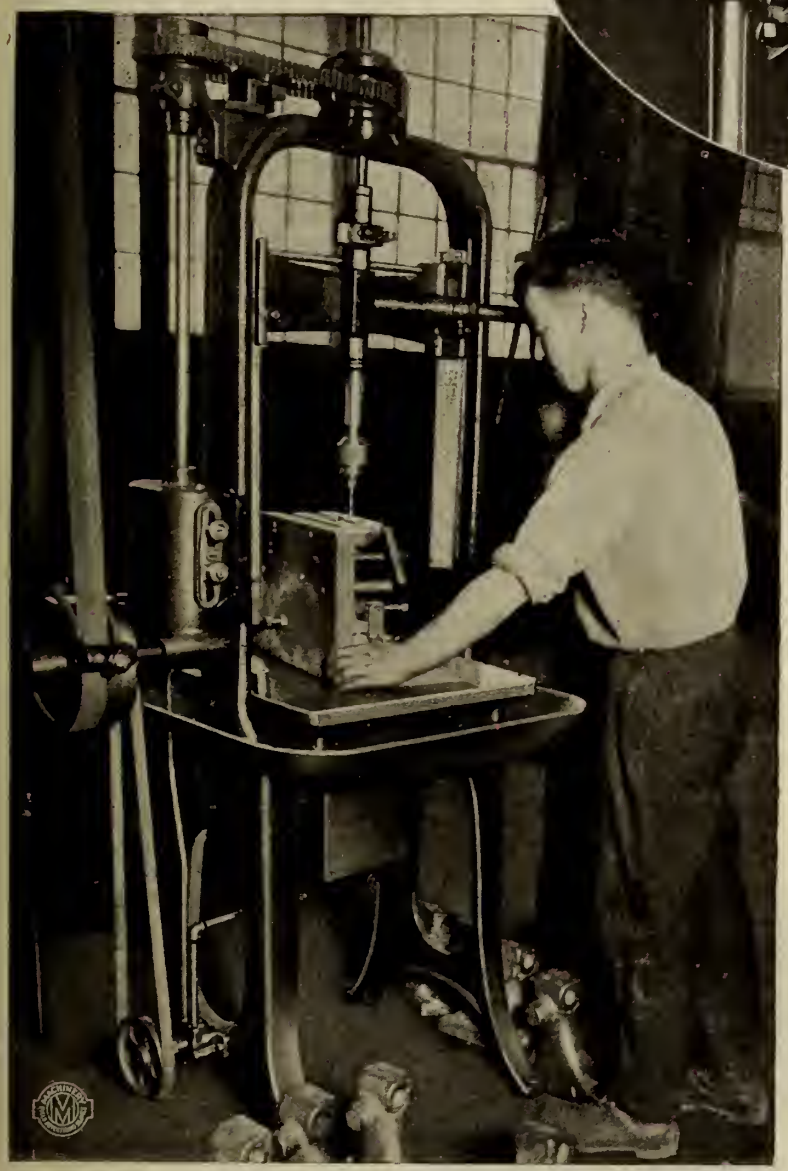
The Drive for High Speed or Heavy Service





Gearing in this capacity would be noisy and would depreciate rapidly. Belting would necessitate a large idler and the power loss would be prohibitive. Chain is the answer to a problem of this kind—Morse Chain.

There are Reasons Why This New Drilling Machine is Driven by Morse Silent Chain

This new drill is a product of the Edlund Machinery Co., of Cortland, N.Y., and is designed for heavy duty drilling at high speeds.

As may be seen, a vertical drive shaft parallel to the drill spindle extends upward from the feed change box to the top of the machine.

From this point a 1" Morse Silent Chain transmits power to the vertical shaft which drives the drill spindle. The sprocket on the drive shaft has 37 teeth, that on the drill spindle 25.

With the drive pulley running at 500 R.P.M., four spindle speeds are obtained —380, 660, 950 and 1215 R.P.M.

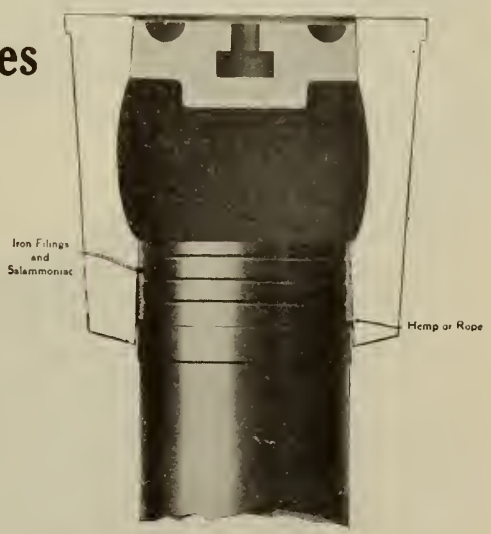
Economiser Tubes

Cr oss Section of Patented Top Header Showing Internal Lid Construction.

are carefully cast in vertical d r y s a n d moulds from a mixture giving a tough, close-grained casting which has proved to be most effective in resisting corrosive action of the gases. After removing from moulds the tubes are carefully cleaned, inspected and hydraulically t e s t e d f o r strength and defects.

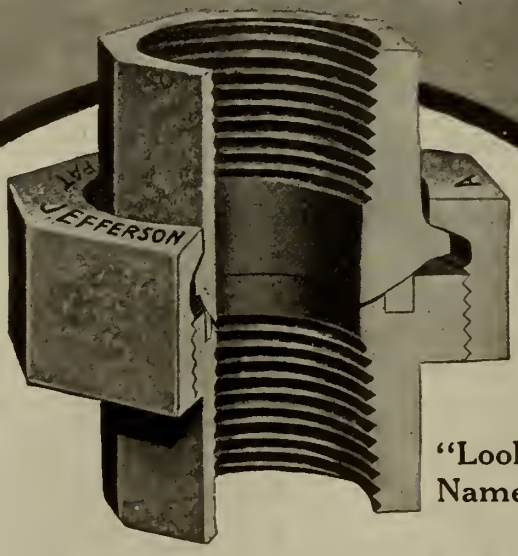


Repair Tube and Cross Section of Header Showing Iron filings and Salammoniac Rust Joint.

The right hand cut shows the method of joining tubes and headers. The tapers at either end of the tube are in opposite directions with the smaller diameter at the ends of the tube. The left ha nd cut shows the method of making the joints for repair tubes.

GREEN'S ECONOMISER, LIMITED, TORONTO

JEFFERSON



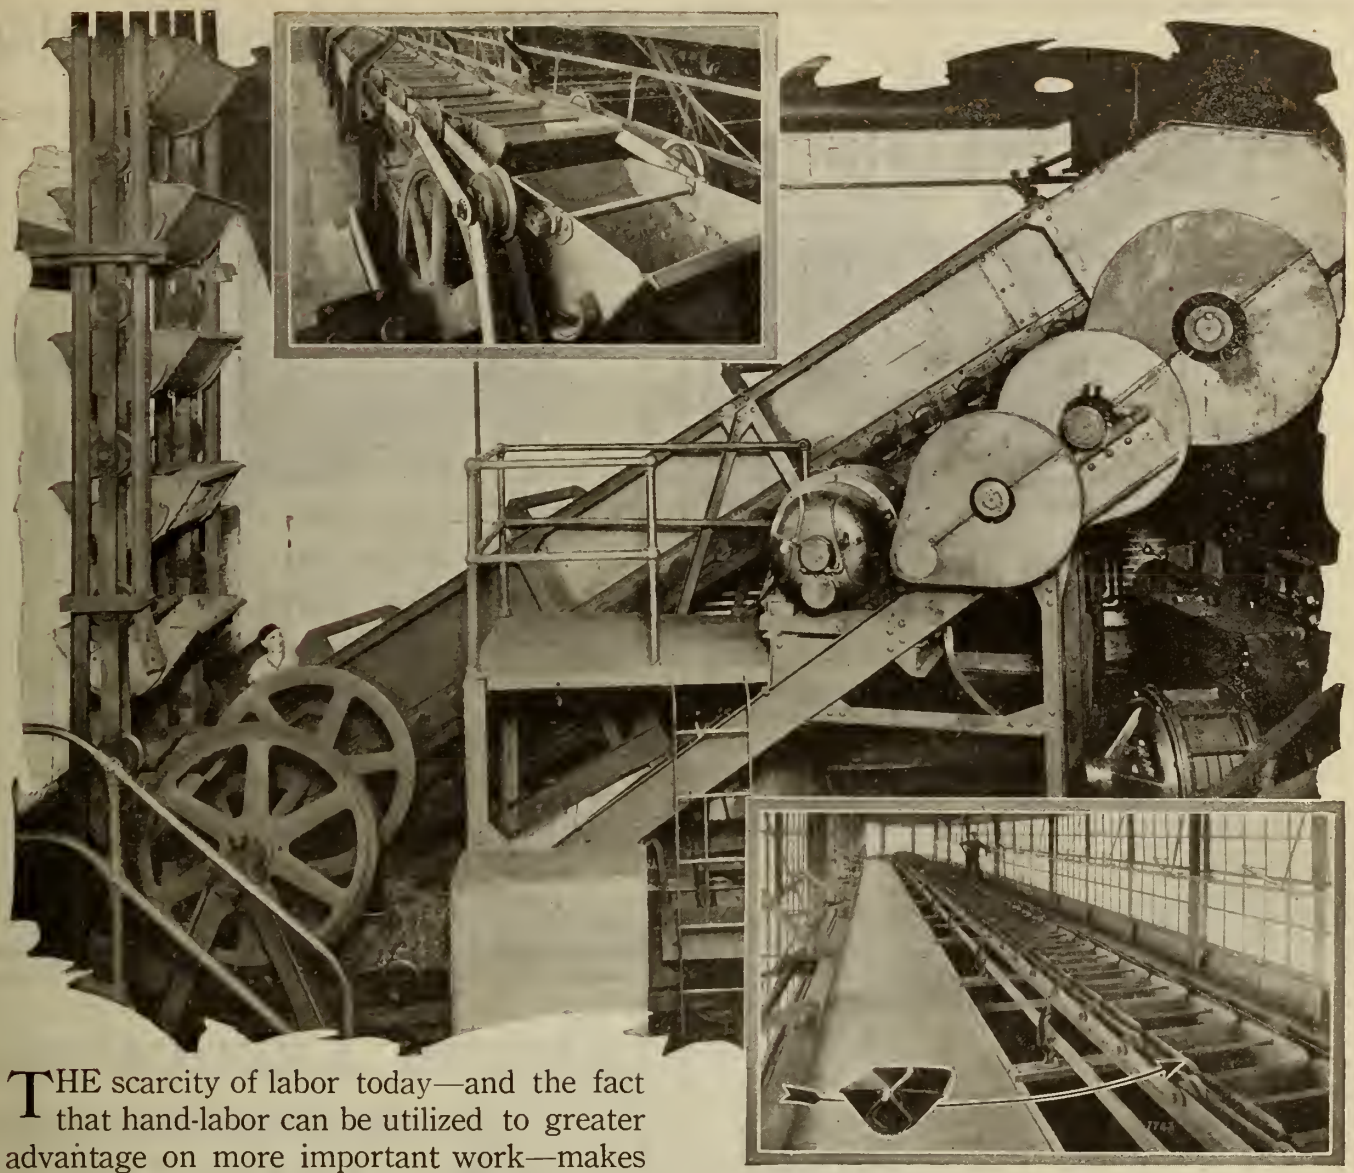
"Look for the Name on the Nut"

JEFFERSON UNIONS are particularly adapted to the requirements of underground pump service. The Brass Seat Ring makes a tight brass-to-iron joint which cannot corrode, and is easily disconnected. The Spherical Ground Joint takes care of alignment difficulties and makes possible a tight joint even if the line is not exactly straight.

And there are other important reasons why JEFFERSONS are better. "The Name on the Nut" protects you against substitute "just-as-good" unions. You would have a mighty hard time trying to make tight a leaky union with a "just-as-good" promise.

Ask your Jobber and JEFFERSONS. He knows every union that's made and can tell you just why JEFFERSONS are better. Write TODAY for our Catalog "UNIONS"

The Jefferson Union Co.
Lexington, Mass.



THE scarcity of labor today—and the fact that hand-labor can be utilized to greater advantage on more important work—makes the purchase of Link-Belt Elevating and Conveying Machinery for handling coal and ashes in the boiler plant, a most profitable investment.

You can save more money by the efficient and economical handling of coal and ashes in your boiler house than in many other parts of your business. Being out of the way—usually in a hot, dusty place—this all-important work is apt to be neglected.

We specialize in designing and building coal and ashes handling machinery. Like all Link-Belt Equipment it is ruggedly constructed; built for hard service, and fully guaranteed.

Let us suggest a Link-Belt Coal Handling installation for your Boiler House. Write for catalog No. 220.

THEIR efficiency holds over half the world's trade.

Makers of Stewart Carburetors.

CANADIAN DETROIT LUBRICATOR COMPANY, LTD.

WALKERVILLE, ONT.

The 2-Part Trap

TWO major parts make up this distinctively simple trap: the body, with inlet and outlet connections; the cover, in which the Dunham Thermostatic Disc is securely fastened.

This disc of special phosphor bronze contains a fluid which is extremely sensitive to temperature changes over a wide range—10 pounds of pressure to 15 inches of vacuum.

Temperatures above normal close the trap; temperatures below normal open it for the escape of the troublesome air and water.

Should it ever become necessary to renew a trap, the cost is confined to the top part only. Just screw a new one into place. Judging from some of the original traps (installed 15 years ago) we do not anticipate much demand for new tops.

The complete story of Dunham Heating Service is quite interesting. Write for it.

6—DISCHARGE VALVE

By painstaking design both light weight and double thickness at wearing surfaces have been obtained in Norwalk compressor discharge valves. Abundant area is allowed for the passage of air or gas around and through the valves. All cushioning consistent with rapid, efficient action is provided.

One feature is worth careful note. The valves are placed in the *cylinder heads*. Thus the shortest possible post and least dead space is obtained. This also allows the water jacket on the gas cylinder to keep maximum length.

New bulletins on Air, Oxygen, Hydrogen, Acetylene and Carbonic Acid Gas are ready. *Tell us where to address your copies.*

VULCABESTON

Is the Alien a Menace?

IN the October issue of MACLEAN'S MAGAZINE a strong presentation is made of the reason why the people of the West are against further foreign immigration.

"The Menace of the Alien" depicts the foreign problem in the Canadian West as it exists to-day, and shows every one of us why we must Canadianize our Ruthenians, Austrians, Slovaks, and our fifty-seven other varieties before we allow any further "unrestricted" immigration.

This article is written by a member of MACLEAN'S MAGAZINE staff who has just returned from a careful, personal investigation of the situation. Shall we have a "White West?" Many Westerners are demanding it. Are the aliens to swing labor into the bosom of the O.B.U.? It is being done—and what must we do to stop it?

The "inside" story of the routing of the Drumheller miner aliens by returned Canadian war veterans is here told by MACLEAN'S for the first time. What leadership must be substituted for the O.B.U. leadership of these foreigners?

The October issue of MACLEAN'S is a Western number in the sense that it contains many articles and stories of distinctly Western interest. For instance:

X "Those Pesky Farmers Out West"

By Hopkins Moorhouse, Author of "Deep Furrows"

They have completely upset the old order of things. No longer will politics consist of the comfortable fight between the Ins and Outs with the old party lines maintained. The grain growers on the Prairies have upset the calculations of the professional politicians and completely changed the face of Dominion politics.

X "Fifty Years in the West"

By Professor W. T. Allison

A breezy and readable sketch of the business career of Winnipeg's veteran business man, James H. Ashdown.

"Further Discoveries of New Land"

By Vilhjalmur Stefansson

The final and most interesting instalment of Mr. Stefansson's story of his wonderful trip of five years' duration in the Canadian north in which he tells for the first time of finding new continents in the Arctic and hoisting there the Canadian flag.

X "The Banshee Bell"

By Edith G. Bayne

A bright love story laid in the mountains of British Columbia.

Other Splendid Features of October MacLean's

X "The Turmoil at Ottawa"

By J. K. Munro

A comprehensive survey of Dominion politics, written with complete impartiality and absolute candor. It is bright and breezy, with a knock in every line for the politicial opportunists. It plucks many tail feathers from our party leaders.

"Spanish Doubloons"

By Camilla Kenyon

The start of a bright and fascinating serial story by a brilliant young writer. It is the Spanish Main brought up-to-date, treasure hunting with a background of fun and romance.

"The Airy Prince"

By Arthur Beverley Baxter

A complete novelette in which is presented a bird's-eye view of England in time of war. It is one of the most brilliant stories that has been written of recent years.

"His Majesty's Well-Beloved"

By Baroness Orczy

The latest novel by this popular authoress appearing exclusively in MACLEAN'S.

"Ebb and Flow"

By C. W. Stephens

A strong business story laid in the province of Quebec.

When Buying Thermometers

There's Just Three Things to Remember—

First, you must have accuracy and sensitiveness—
Second, durability is absolutely essential—
Third, the thermometer must be suitably constructed for the intended application.
Accuracy, sensitiveness and durability are absolutely guaranteed in

"Crescent" Thermometers

And with nearly seventy years of experience to our credit, we are qualified to properly interpret your needs.
Our Catalog P.H. 200 illustrates and describes "Crescent" Thermometers for every application. Also test thermometers, glass thermometers, etc.
Get a copy of Catalog P.H.-200 to-day.

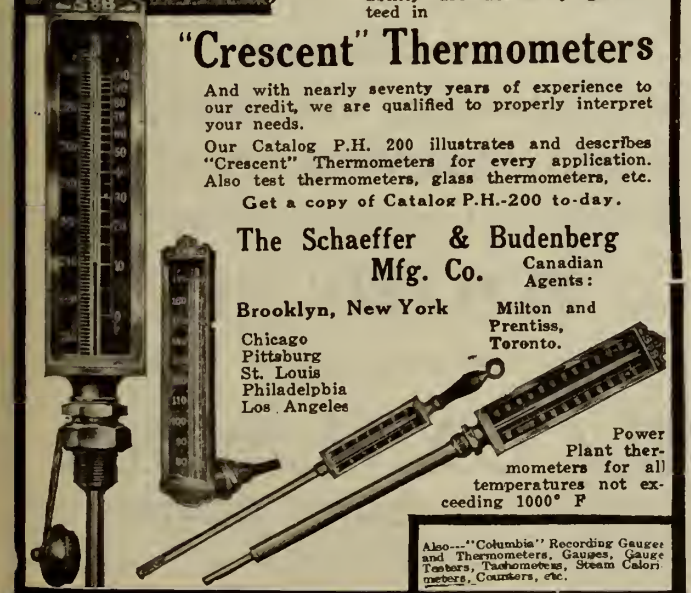
Milton and Prentiss, Toronto.



Power Plant thermometers for all temperatures not exceeding 1000° F

Also—"Columbia" Recording Gauges and Thermometers, Gauges, Gauge Testers, Tachometers, Steam Calorimeters, Counters, etc.

Cast Iron Screwed Fittings

Standard Weight

These fittings are of good design and weight, and are suitable for steam working pressures up to 125 lbs., or water working pressures to 175 lbs.

Straight Elbow

Straight Tee

All sizes, ¾" to 6" inclusive, carried in stock.

EXTRA HEAVY CAST IRON SCREWED FITTINGS

Straight Elbow

Straight Tee

250 pounds working pressure. All sizes, ¾" to 6" inclusive.

What They Say About Power House

"I certainly am in favor of a semi-monthly publication. In my opinion it cannot be published too often. I have been several times around the world as an engineer in the British Merchant Service and POWER HOUSE is the best paper of its class I have ever met."—Mr. Percy S. Hunter, Donavon, Sask.

"I would like very much to get POWER HOUSE twice a month. For Canadian engineers it is unexcelled."—Mr. A. R. Troke, Paris, Ont.

"New subscribers who do not really know the value of POWER HOUSE might demur at paying a high price for it, but personally speaking, I would not object to paying double price for double service. I never miss reading the advertisements. They are real interesting to anyone in this line."—Mr. Fred E. Reesar, Municipal Electric Light Plant, Markham, Ont.

"I feel that a semi-monthly magazine will also be a great step in our favor inasmuch as we can now look forward to a friend and adviser's call twice a month instead of once. I take a number of magazines myself, but there is none I look forward to receiving like my old friend and adviser, POWER HOUSE."—Mr. L. E. Wight, Drumheller, Alberta.

"I favor the change to semi-monthly. It is worth twice the money to a Canadian engineer when compared to other magazines published in the U.S.A., upon which I am basing this suggestion."—Mr. Fred R. McNeil, Shawinigan Falls, Q.

"I am very pleased to hear that POWER HOUSE is to be published twice a month as I have been a reader of it for several years. The change will be a great help to engineers."—Mr. W. E. Dale, Vancouver, B.C.

and Hundreds More Say the Same

Renewal subscriptions are now being received at the price of One Dollar per year for any number of years. Send in yours NOW. Don't wait until your present subscription expires. The One Dollar rate will not last much longer.

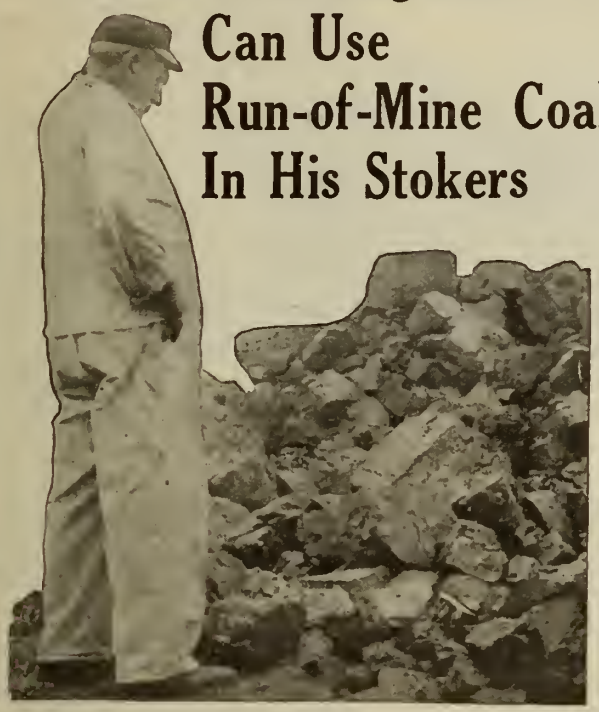
How Your Engineer Can Use Run-of-Mine Coal In His Stokers



Every indication points to a coal shortage before Winter sets in. To increase production, the coal operator will ship the size most easily loaded, Run-of-Mine. As a result, screenings cannot always be secured when needed.

"But," says **your ENGINEER,** "our Boiler plant is equipped with automatic stokers—and to make steam we have got to have coal of the right size—we can't use Run-of-Mine."

You can insure him a constant supply of stoker coal by installing a JEFFREY SINGLE ROLL CRUSHER in your plant.

A single operation of this crusher will reduce Run-of-Mine to the proper size for your stokers.

Bulletin No. 141-4 gives complete information why the Jeffrey Crusher safeguards your coal supply, and eliminates the worries of buying properly sized coal. SEND FOR COPY.

The ULTIMATE in Blow-off Valves

The "Duro" has demonstrated its peculiar adaptability as a blow-off by many years of satisfactory service, with a minimum cost for upkeep.

The self-cleaning seat feature prevents an accumulation of sediment on the seating faces during the blow-off, thereby reducing wear to a minimum and preventing leakage while the boiler is in operation.

To further enhance the durability of the valve, the disc is reversible; the disc faces can easily be replaced with new material in case of wear, and all the parts including the seat ring and reversible disc are renewable.

The materials and workmanship are of characteristic Lunkenheimer "Quality."

Specify Lunkenheimer "Duro" and insist on their installation.

Write for descriptive booklet No. 515DC.

Howard Guided Expansion Joints

Howard Guided Expansion Joints put the "How" in all expansion problems. The high pressure and superheat of modern engineering practice have added tremendously to pipe line dangers and the engineer's troubles.

"How" to take up the greatly increased expansions and contractions while at the same time keeping joints tight under the greater pressures?

That is the question to which HOWARD Guided Expansion Joints are the exclusive and satisfactory answer.

MAXIMUM OF TRAVERSE is the first essential of an expansion joint. Here the HOWARD excels with its full 4 inches of play between the "cold" position (see cut above), and the "hot" position. Assuming the outside temperature is 32 degrees, this 4 inch play amply takes care of the linear expansion in more than 100 feet of wrought iron pipe at any pressure from 30 to 300 pounds. Very often one HOWARD, by its greater capacity, takes the place of two or more other expansion joints.

Inquire about this to-day.

Scale in Your Boilers

is an unprofitable boarder. Its appetite is enormous and it consumes far more than it is worth. Why not give it TWO MONTHS' NOTICE, and put an end to your loss thereafter?

THE SIXTY-DAY TEST OF METLSKIN is open to any reliable concern that is troubled with boiler-scale, pitting or corrosion. A small daily dose of METLSKIN, for a period of two months, will bring down the most tenacious scale, and absolutely convince you that A CLEAN BOILER IS NOT ONLY POSSIBLE, but EASY.

SEND A POSTCARD for the METLSKIN booklet and learn about Our Offer, Guarantee Bond, and Prices.

METLSKIN is neither "Compound" nor "Cure-all."

Clean Tubes Mean Coal Saving

And easier firing, less ash-handling, fewer shut-downs, prevention of bagged or burned tubes, fewer repairs, and less frequent wash-outs. METLSKIN can pay for itself in a short time.

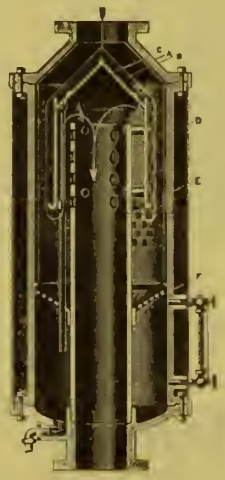
III IMPORTANT THINGS

TO CONSIDER ABOUT
A SEPARATOR



I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE—Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION—Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

Sweet's Separators

A Rugged Pulley-Gripper

There is nothing like leather for belting, and SparOak Leather Belting has peculiar advantages all its own.

SparOak is a two-in-one belt combining rugged strength with unique pulley-grip. Its great endurance and minimized slip make it a double-service belt of unusual qualities.

Two kinds of leather enter into a SparOak Belt. The outer ply is oak tanned, cut from the best selected center stock. The ply next the pulley is Graton & Knight Spartan leather, tanned to give pliability and traction power unequalled by any other material.

SparOak Belting

Here is an 18" SparOak Belt on a hard drive in a warm, moist atmosphere where the extreme flexibility of Spartan and the firmness of Oak leather are necessary.

SparOak is the answer to a great many perplexing belt problems, saving power and standing up under the most severe conditions.

If you have a troublesome belt drive, consult us as to what belt is required. Maybe it is SparOak, but in any event one of the Graton & Knight Standardized Series of Belts will fit exactly. Write for our booklet on Standardized Belting.

SparOak Belts grip from the start. During the weeks most new belts take to "work in," a SparOak Belt is giving full power and keeping production up to normal. And SparOak Belts keep on gripping for years under adverse conditions. They withstand repeated shifting, and the wear against step cone or flange pulleys. They render efficient service on drives with high speeds, small pulleys, and heavy loads. In short, any of the factors that quickly wear out ordinary belts affect SparOak belting amazingly little.

No Buckling
Split Tubes
Nor Leaky Heads

Because in this Alberger Heater expansion stresses are positively overcome by the use of a divided tube head which takes care of the unequal elongation of the tubes in the various passes.

With this
ALBERGER MULTI-HEAD HEATER

your hot water cost will be cut down. You will be saved steam repairs—fuel—space. You will need no extra storage tank because the water will be heated to the required temperature as fast as it is withdrawn.
You will need less fuel because the small diameter helically corrugated seamless pure copper tubes insure very rapid heating; they have been proven to transmit 50% more heat than any plain tube heater of similar size.

Send for Bulletin No. 201

Capacities range from 200 to 200,000 gallons per hour.

DURABLA
TRADE MARK REGISTERED

STRENGTH—GOODNESS—QUALITY
STANDARDIZATION

During the past few weeks we have presented facts relating to the performance of DURABLA sheet in all main services where gaskets are essential—air, water, oil, steam, ammonia, gasoline and acids. That DURABLA successfully withstands extreme conditions in all of these particular services is proof that it is one material for every condition of every service, and that it is all that is implied by the term "standard."
In order to standardize on a gasket material it is necessary to determine by test to your own satisfaction the fact that a certain material meets all your specific requirements.
DURABLA Gasket Material in any quantity will be shipped to you under money back guarantee that it will make a tight joint wherever a permanent gasket is required.

One Standard material for all gasket work—Sold on a Service Basis.

WHAT!
Throw away a good Pair of Shoes that could be Half Soled!

Absolute extravagance! And yet, thousands upon thousands of valves are discarded every year—only partly worn out. A needless waste that could be prevented by the installation of

Pratt & Cady
Renewable Disc Globe Valves

When the old asbestos disc of a P. & C. "Renewable" is worn out, it can be replaced in a few minutes without removing the valve from the pipe line—at a fraction of the cost of a new valve. Just like half-soling a pair of good shoes. And once more your valve is ready for a long term service—as good as new.

The *next time* you have a valve breakdown replace that valve with a Pratt & Cady "Renewable." A long-wear valve outside of its renewable feature.

Made in all sizes and for every kind of service. Remember, NEXT TIME!

Write today for our Valve Catalog and be ready for an emergency

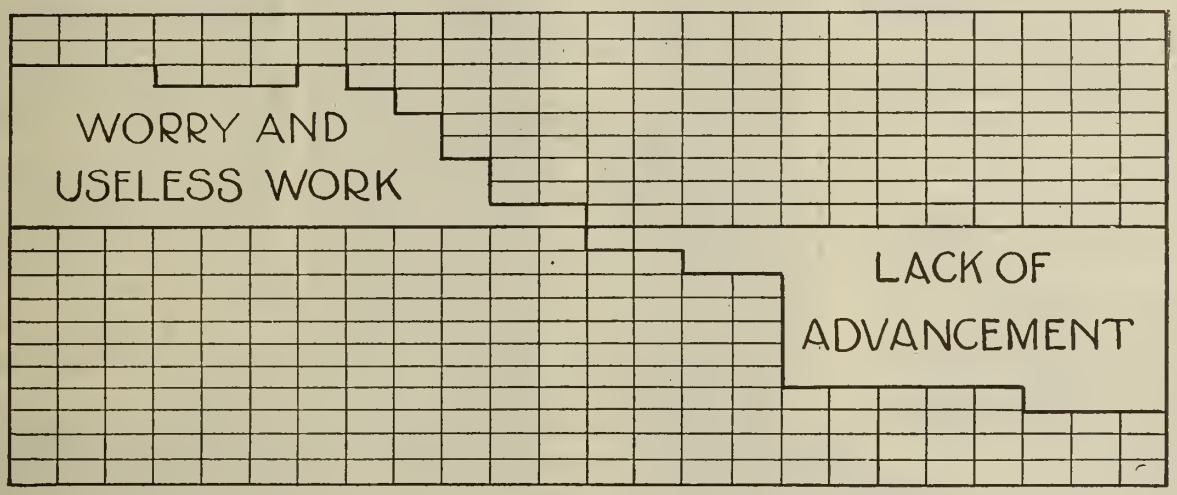
Let the C.A.S.E. Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

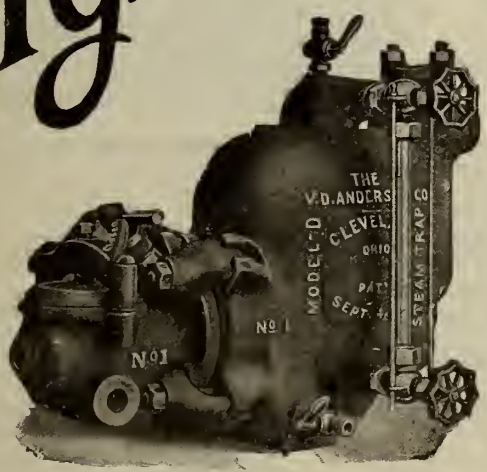
Stays Tight



The ANDERSON Model "D" Steam Trap

Just think of the satisfaction you have once this perfected trap is in your steam-room!

Tight from the day you put it in! Of that you can be sure.

It is operated by a counterbalanced Lake Superior Copper Float. Its large air valve is ever under deep water seal, and never will it wire draw.

Furthermore, every part is machined to solid gauge. Self-contained strainer and self-contained by-pass are Anderson features. Note the outside gauge glass. And the simple design! It gives you complete accessibility to every part.

Write for full particulars.

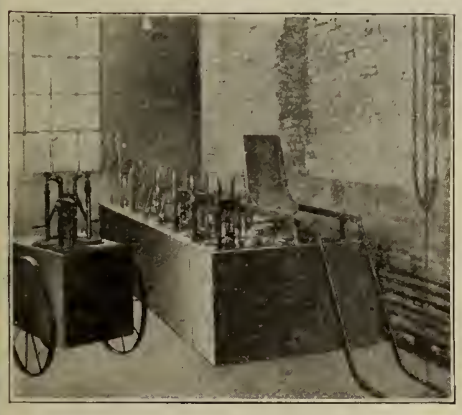
Stop Wasting That Oil !

You don't allow castings, finished parts or supplies to lie around without an accurate record of them. Such things go into the store room, carefully checked in and charged out as used—Why?—It is the only safe, systematic way to do.

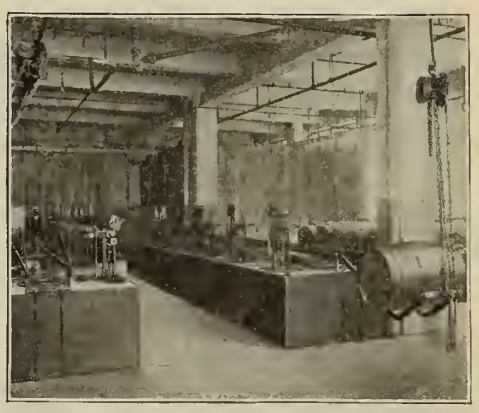
Are your oils handled as carefully? They can be, and can be accounted for as easily as other materials—receipts checked, accurate quantities given out, charges made to the departments using and records kept if desired.

BOWSER ESTABLISHED 1885 Storage Systems



BOWSER Lubricating and Paint Oil Battery Installation with Portable Outfit for Lubricating Oil

Save the Oil



Double Battery Installation for Paints and Other Oils, one unit or as many as needed can be installed.

Bowser Systems enable workmen to get full value from every drop of oil, save a great amount of time and labor in handling.

Put your Oil storage problems up to the Bowser engineers. Let them make a survey of your plant, show you just what you may expect to save by the use of Bowser oil handling equipment. It costs you nothing and it should mean a saving for you. *Write us today for further information.*

DEFENDER

DUPLEX DRAFT GAUGE

The Peer of Them All

Price $20.00

They read: Draft over the fire. Draft at the last pass of the Boiler and the differential through the Boiler.

THE FIREMEN CONTROL the fires by the readings on the Gauge. It shows every condition of the Fires and Boilers, except Flue Gas Temperatures and the Defender Flue Gas Pyrometers show the Flue Gas Temperatures. Also see the Defender CO_2 Analysers, put up in permanent case so as to take a reading for CO_2 in less than one minute's time. Write for Bulletin No. 100.

Defender Catalogue No. 11 shows the largest assortment of Combustion appliances, efficiency instruments and damper regulators made. We can help you save fuel.

WE STRIVE TO EXCEL

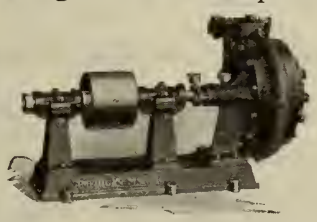
DEFENDER AUTOMATIC REGULATOR CO., 709 Pine St., ST. LOUIS, MO.

AMERICAN-MARSH PUMPS

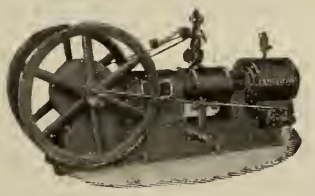
SIMPLE **RELIABLE** **EFFICIENT**

The American-Marsh steam pump is an improved form of the famous Marsh Pump which has been on the market for over thirty years, during which time over 150,000 have been manufactured and sold.

The American-Marsh Pump has no internal stuffing boxes, no tappets and no slide valves. The auxiliary valve is of the semi-rotative disc type of an improved design. The main steam valve is of the balanced piston pattern, assuring highest efficiency. The water ends have large valve areas and are fully bronze fitted, including solid bronze piston rods and bronze removable water cylinder bushings.



American-Marsh Centrifugal Pumps are made with the same high grade of material and workmanship which characterizes the construction of the steam pumps. They are made in all sizes up to 12 inch, both single and two stage for heads up to 250 feet.



The line also includes—

Power Pumps	Jet Condensers
Deep Well Engines	Dry Vacuum Pumps
Air Compressors	Boiler Feed Pumps

Tires Led the way to Better Hose

THE hose industry stretches back into the early days of rubber history.

For year after year rubber hose had been built upon the immature principles of those early days.

But Goodyear has developed new and higher standards of hose efficiency.

Just as broad-visioned Goodyear chemists and engineers cut loose from tradition and built tires in a better way, so have they built industrial hose.

Old processes—obsolete methods have been forgotten. Only those processes, formulae and methods proved by service tests and experiment to be best enter into the manufacture of Goodyear Industrial Hose.

Hose linings which do not crack or harden have been developed.

Outer covers with an exceptional degree of toughness to withstand the wear of severe industrial service—another distinctly Goodyear feature.

In a word, Goodyear has built better hose. Original cost did not count if greater final economy and increased efficiency were a sure result.

You cannot know how far short of complete satisfaction ordinary hose falls until you experience the greater perfection of Goodyear Industrial Hose.

Give Goodyear Hose a trial now. There is a particular Goodyear Hose for every industrial purpose—water, steam, pneumatic tool, air drill, railway, fire, suction, etc.

Phone, wire or write to the nearest branch for a man trained in hose problems to study your needs. No obligation.

The Goodyear Tire & Rubber Co. of Canada, Limited

Halifax, St. John, Quebec, Montreal, Ottawa. Toronto, Hamilton London, Winnipeg, Regina, Calgary, Edmonton, Vancouver.

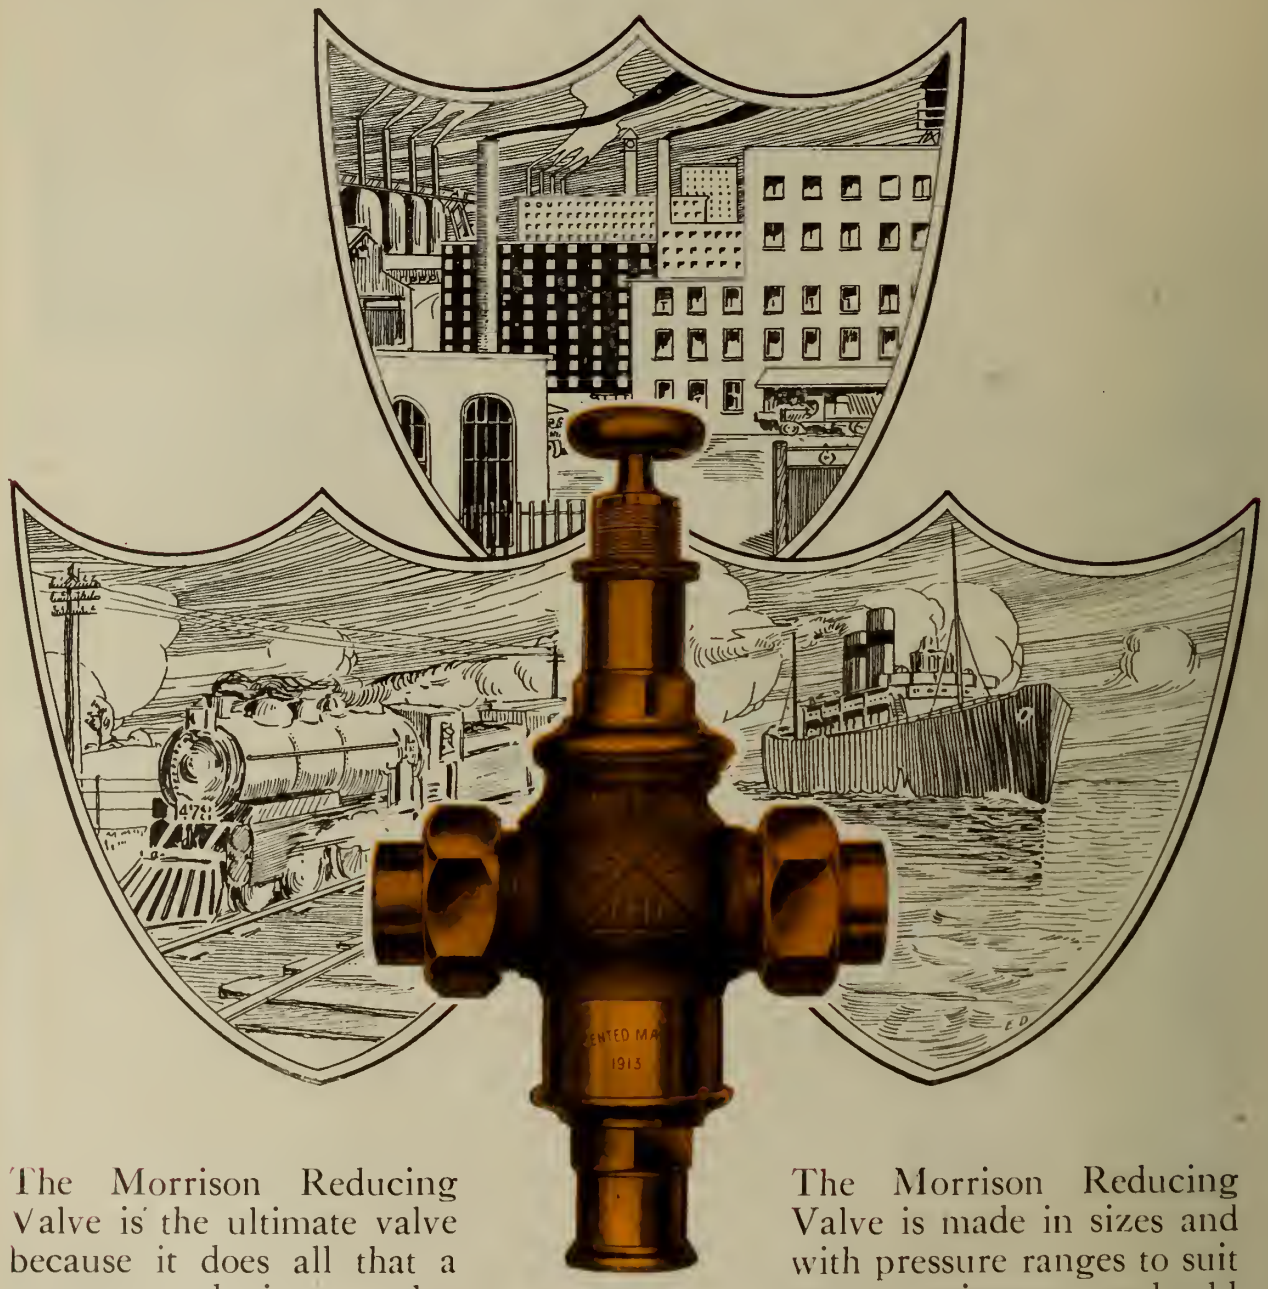
INDUSTRIAL HOSE

REDUCING VALVE PERFECTION



The Morrison Reducing Valve is the ultimate valve because it does all that a pressure-reducing valve could possibly do. It makes no difference how the initial pressure varies, the J.M.T. will keep the low pressure constant.

THE VALVE FOR EVERY SERVICE

The Morrison Reducing Valve is made in sizes and with pressure ranges to suit every requirement, and sold with the well-known Morrison guarantee. We will be glad to prove our claims. Write to-day for our booklet on Reducing Valves.

The James Morrison Brass Mfg. Co., Limited

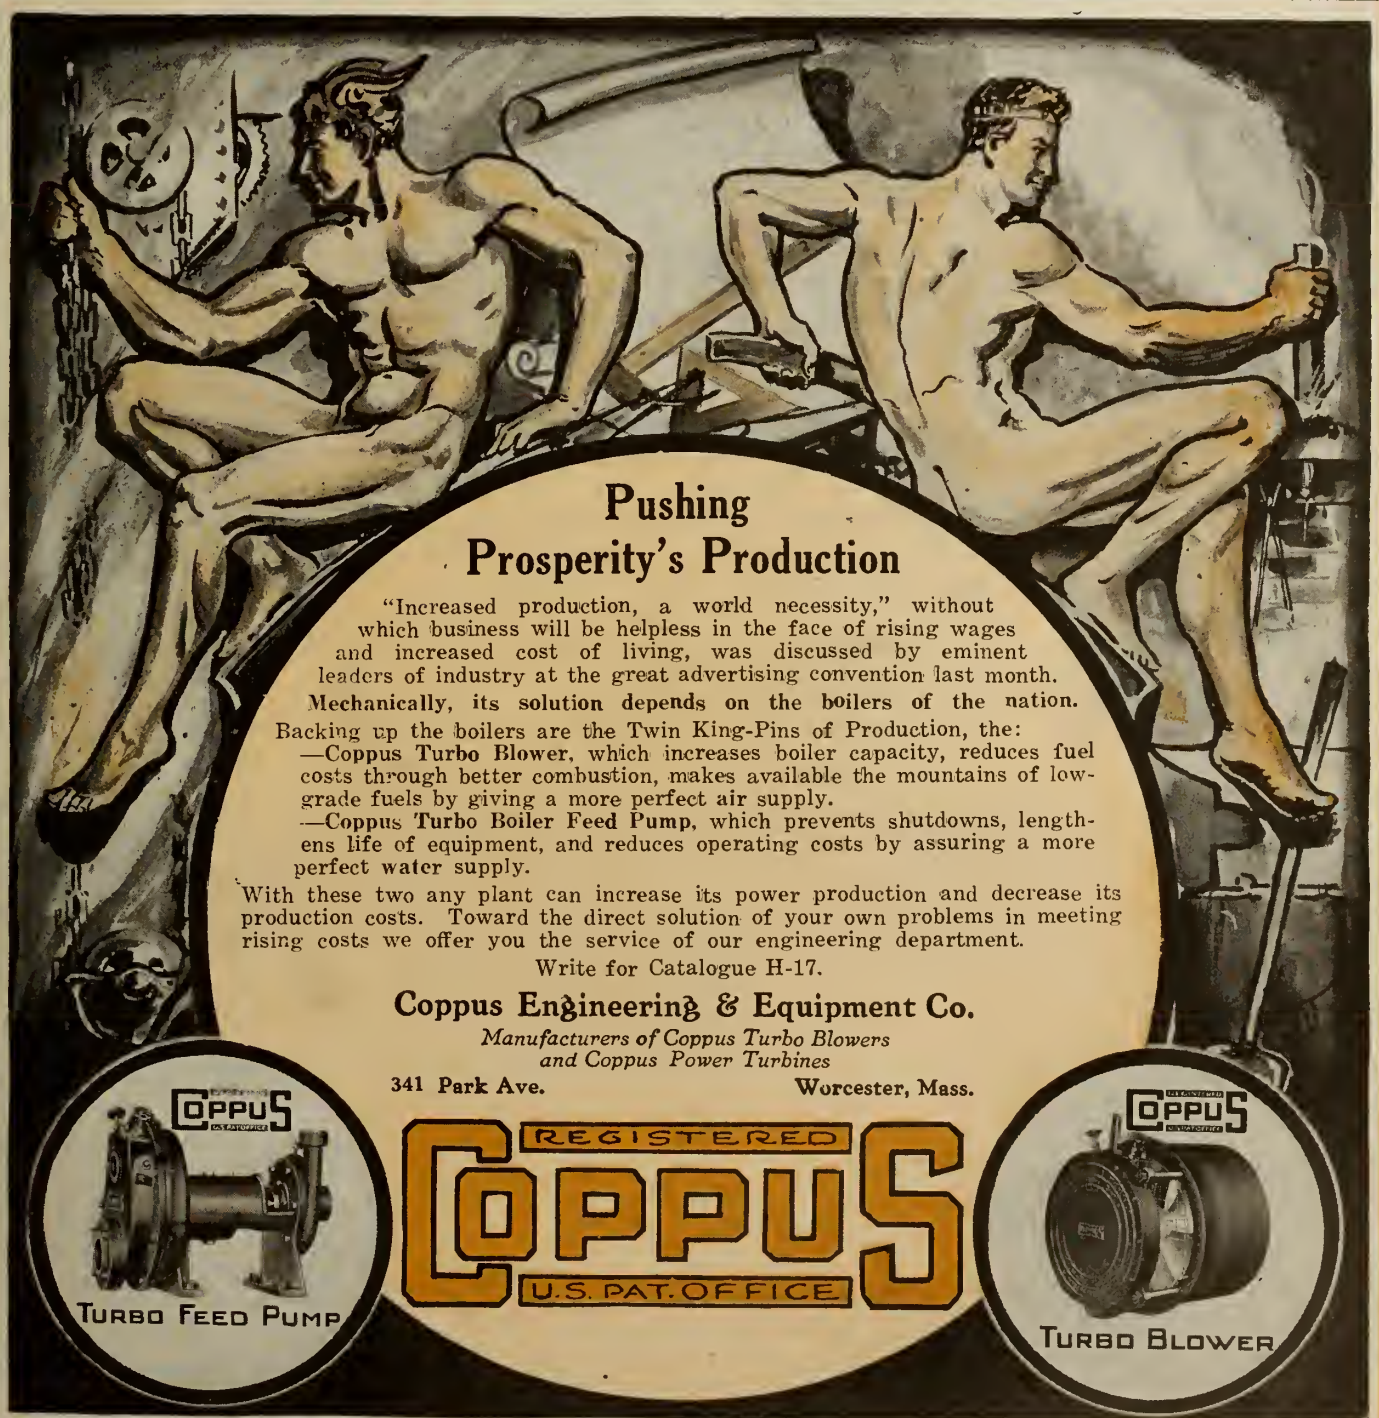
ANNUAL DIRECTORY NUMBER

POWER HOUSE

A semi-monthly newspaper devoted to the Generation, Transmission, and Application of Steam, Gas, Electric, Air and Water Power; and to the operation of Refrigerating Machinery.

Published by The MacLean Publishing Company, Limited, 143-153 University Ave., Toronto
MONTREAL: Southam Bldg. LONDON, ENG.: 88 Fleet St., E.C. WINNIPEG: 1103 Union Trust Bldg.

Vol. XII.—No. 17. Publication Office, Toronto—October 20, 1919 Published Semi-Monthly $1.00 per Year



Pushing Prosperity's Production

"Increased production, a world necessity," without which business will be helpless in the face of rising wages and increased cost of living, was discussed by eminent leaders of industry at the great advertising convention last month.

Mechanically, its solution depends on the boilers of the nation.

Backing up the boilers are the Twin King-Pins of Production, the:

—**Coppus Turbo Blower**, which increases boiler capacity, reduces fuel costs through better combustion, makes available the mountains of low-grade fuels by giving a more perfect air supply.

—**Coppus Turbo Boiler Feed Pump**, which prevents shutdowns, lengthens life of equipment, and reduces operating costs by assuring a more perfect water supply.

With these two any plant can increase its power production and decrease its production costs. Toward the direct solution of your own problems in meeting rising costs we offer you the service of our engineering department.

Write for Catalogue H-17.

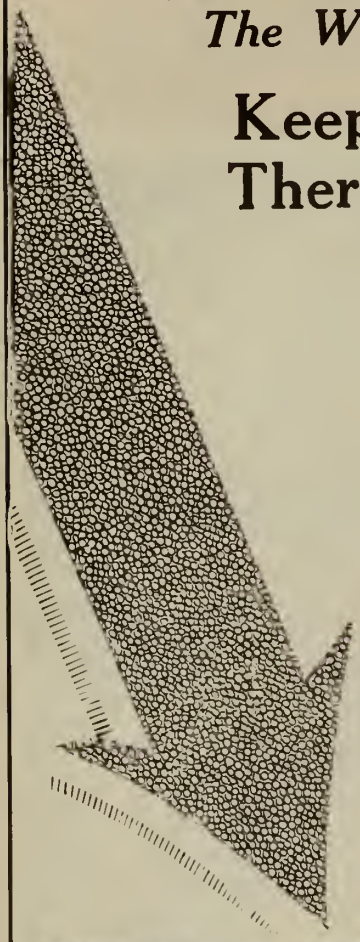
PYRO PUTTY

TRADE MARK REG U S PAT OFF

FIRE BRICK IN PUTTY FORM

The World's Best Furnace Lining Material



Keeps Hot Air In and Cold Air Out Thereby Increasing Furnace Efficiency

Pyro Putty is far more durable than standard fire bricks for making new furnace linings, because it is not weakened by a multiplicity of fire clay joints.

And for repairing worn furnace linings, Pyro Putty will prove ECONOMICAL, because repairs can be made quickly by unskilled labor. Simply pound the material in place with a mallet, smooth it off with a trowel and the job is done.

Pyro Putty is put up ready for use, in 700-pound barrels, a barrel being equivalent to 100 standard fire brick.

The sketch below represents the fire box of a water tube boiler lined with Pyro Putty. Compare it with your own fire box linings; then

Order a few barrels and keep them on hand for emergency repairs.

A few barrels of Pyro Putty should be part of the emergency equipment of every steam power plant.

Write today for further information and prices

PYRO PRODUCTS COMPANY

The Jones Underfeed Stoker

Cuts Fuel and Labor Cost—

Coal and labor cost sheets show a remarkable reduction in plants that are equipped with the Jones Underfeed Stoker.

The "Jones" is sure in operation and feeds fuel more economically than any other system of firing. It maintains a uniform steam pressure and responds instantly to varying demands for steam.

The "Jones" construction means durability. No parts move in contact with the fire—no loss of fuel through grates, there are none.

The "Jones Stoker" pioneered and developed commercially the underfeed principle of firing, which is to-day without exception the most efficient method of stoking bituminous coal.

May we send you full facts and figures?

Jones Underfeed Stoker Co., Limited
37-41 Britain Street
Toronto, Ontario

SAVES 15 to 25 Per Cent of Fuel

MADE IN CANADA

They require no brickwork
They burn cheap fuel

They take up only one-seventh the space of the ordinary boiler.

The above are some of the advantages of using the

TALBOT
CONTRA-FLOW
Steam Boilers

Boilers of the water tube type, quick steaming without any large steam or water spaces, making serious explosions impossible. Automatic water and oil control. Tubes easily replaced under reduced steam pressure.

Built in all sizes from 50 to 4,000 H.P.

May we send catalogue?

CATALOGUE ON REQUEST

Waterous

BRANTFORD, ONTARIO, CANADA

You Can Buy Them in Confidence

A catalogue of the features of Diamond Soot Blowers can no more give you a correct conception of the equipment than a catalogue of the virtues of a man can give you an idea of his personality and achievements. But, for those who are interested in some of the details of design and construction which have made Diamond Soot Blowers the largest selling and most depended-upon equipment for their service in the world, we here call attention to certain fundamental and exclusive features.

Calorized Metal: Blower units are constructed of metal treated by the calorizing process. This process renders the metal capable of withstanding continuous temperatures of 1800 deg. F, whereas untreated iron and steel begin to oxidize rapidly at continuous temperatures of 1100 deg. F. This means that Diamond units can be placed in portions of the boiler otherwise inaccessible for cleaning.

Venturi Nozzles: The nozzles from which the steam issues are designed on the principle of the Venturi tube. With identical pressures, steam is emitted at three times the velocity possible from a straight-walled nozzle, thus insuring the absolute maximum in cleaning efficiency.

Automatic Stops: The range of action of the steam jets is absolutely controlled. At no time can they be directed against baffles or brick work, with consequent deterioration of the latter.

General Construction: Stanch, rugged, mechanically correct, Diamond Soot Blowers are noted for their dependability under all conditions of service. Mechanics, materials, design have been carried as far as they can be carried, but having been carried that far, they merge into the soot blower itself, and there the equipment stands complete, a single unit, not a list of features. *Ask for Bulletin 185.*

Industrial Controllers

for

Temperature, Pressure and Time

Applicable to all manufacturing purposes. As applied to:—

RUBBER TRADE:—Vulcanizers, mill-rolls, calender rolls, compound driers, shoe-curing kilns, etc.

WOOD WORKING:—Dry kilns, glue kettles, glue tanks, etc.

POWER-PLANTS:—Feed-water heaters, condensers, steam pressure reduction, water jackets, etc.

TEXTILE MILLS:—Dye tubs, dye kettles, dyeing machines, slashers, steaming boxes, bleaching kiers, etc.

TANNERIES:—Tanning vats, water heaters, etc.

BAKERIES:—Tempering tanks, proofing and storage rooms.

MEAT PACKING:—Hog scalding, boiling tanks, etc.

GASWORKS:—Ammonia and benzol stills, condenser and scrubber temperatures, exhauster and oven offtake controls, tar extractor control, holder seal-water temperature control.

Our bulletins showing instruments as applied to your industry, will be mailed at your request.

Republic Flow Meters

TO MEASURE

Steam, Water, Air or Gas

Indicating, Graphic Recording and Integrating

Use a REPUBLIC Meter to Measure

Steam generated at the boilers.

Steam distributed to departments or sold to customers.

Apply a steam meter to your carbureted water gas sets. It will show the number of Runs, the time of Blow and time of Make Periods, amount of steam used per run and total steam used.

Feed-water, water supplied to departments, total water pumped.

The gas you make, also the gas used by your steel furnaces (coke oven or blast furnace gas).

Measure the air you compress and the amount you supply to your customers.

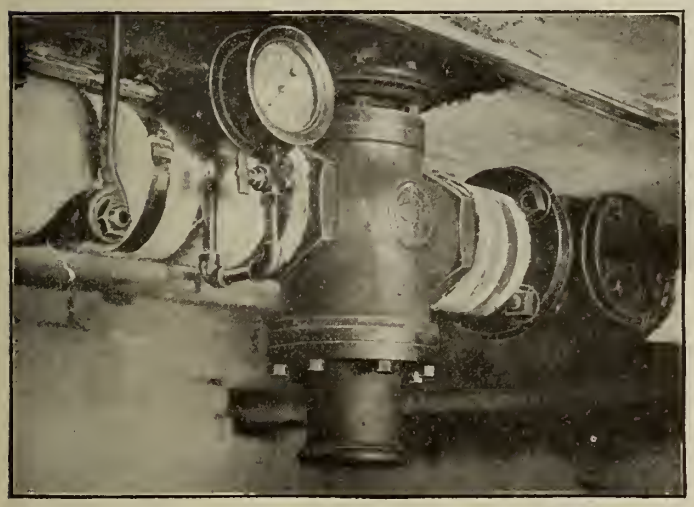
Three Veterans

Here is actual proof of Real Service and Real Value given by

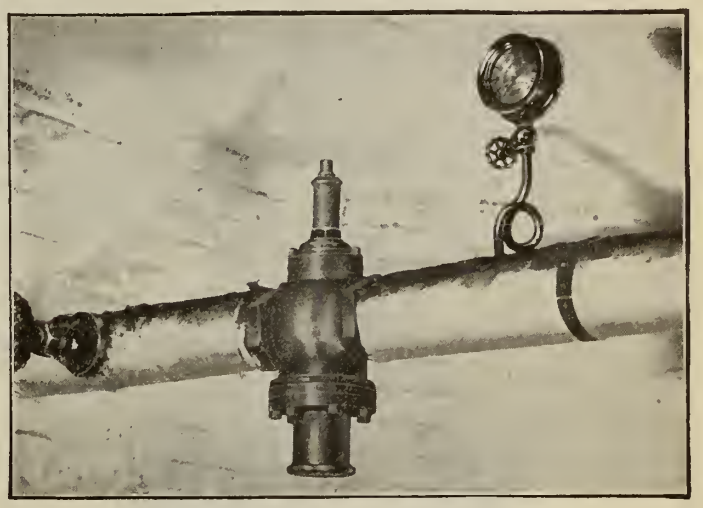
MASON REDUCING VALVES

23 YEARS

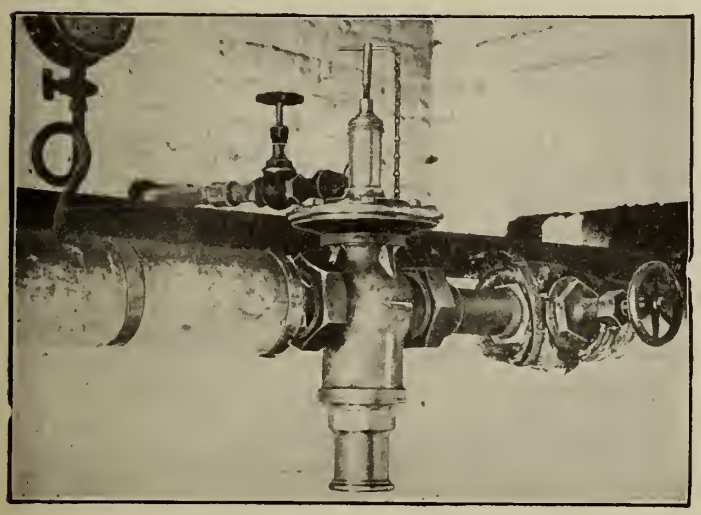
Born in 1896---and "still going strong"



No. 1—3" Mason Standard Reducing Valve.



No. 2—Mason 2½" Standard Reducing Valve.



No. 3—Mason 2" Standard Reducing Valve.

23 YEARS AGO

in November, 1896, two of these valves (Nos. 1 and 2) were installed on the heating system of the Protestant Hospital for Insane, at Verdun, Montreal. No. 3 was installed in 1899.

It was one of the present chief engineer's first jobs. Mr. Thompson found them in the store on his arrival to take charge.

No. 2 and No. 3 have never been taken out of the line. No. 1 was repaired for the first time in September, 1919, requiring new main valve and auxiliary valve.

Such examples are the reason why Mason Valves are **imitated** and **pirated.**

Every dealer and jobber in Canada can supply you with **genuine** Mason Valves.
All genuine Mason Valves are distinguished by the Mason trademark cast on the body.

Steady, Dependable Power

INDUSTRIAL success is based on power—steady, dependable power. Every mechanical unit in your plant—engines, dynamos and machines—must give 100% efficiency and therefore must be carefully and properly lubricated with lubricants of correct body.

When choosing your lubricants, you cannot afford to consider any factor other than quality. Good lubricants, like those in the Imperial line, are always most economical. They cost less per lubricating hour because they last longer; they do not wear or burn out as do poor lubricants.

Imperial Lubricants are right. They never vary in quality and will give you continuous satisfaction and better dollar-for-dollar value. They are made only from the best crudes obtainable and are as perfect as science and experience can make them.

Look over the list on the left. Among those lubricants you will find the right lubricant for every moving part of every machine in your plant. Their use will enable your plant to give steady, dependable power under every service condition.

We invite you to consult with our Lubrication Engineers. Their advice or assistance is yours for the asking. Address us at 56 Church Street, Toronto, or at any of our branches.

Every Part of Every FRICK INSTALLATION Must Be Perfect in order to maintain

FRICK SUPERIORITY

That is why Frick Refrigerating and Ice Making Equipment proves a profitable investment wherever installed.

The entire Frick line, from the smallest to the largest plant, from the smallest part to the largest part in each plant, is designed to meet our strict standard of Durability—Efficiency—Economy. Every part must be perfect in order to maintain the well-known FRICK Superiority.

Therefore, when you purchase FRICK Equipment you are assured of perfect service regardless of the unforeseen overload demand that might be placed on it sometime—assured of continued operation without danger of breakdowns in the midst of a busy season—assured of economical operation at all times—and a long life. Frick Equipment has been standing up under the above conditions for nearly a half-century, day after day, year after year, under the most severe conditions.

You can't go wrong when you specify "Frick Equipment." **Catalog on request.**

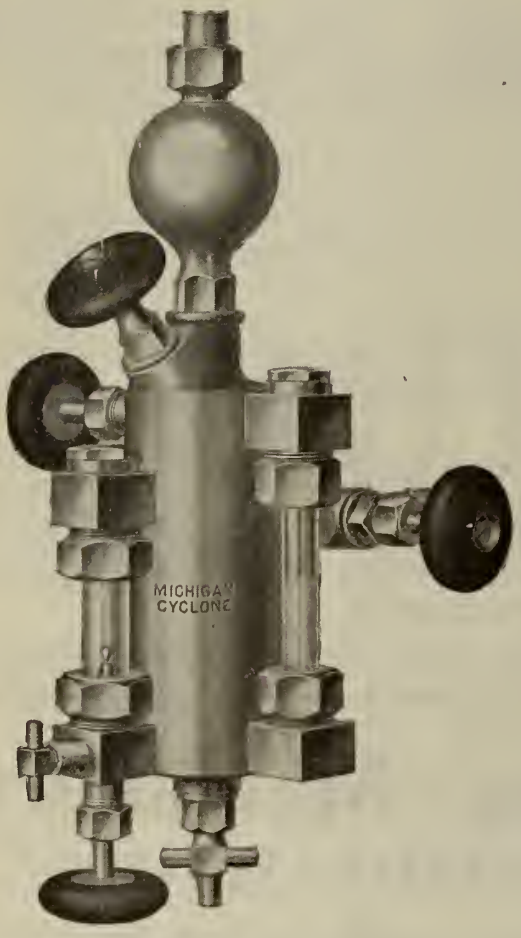
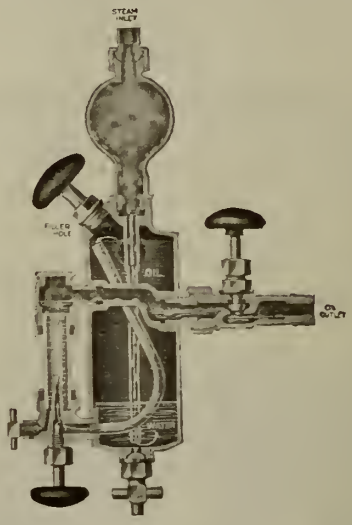
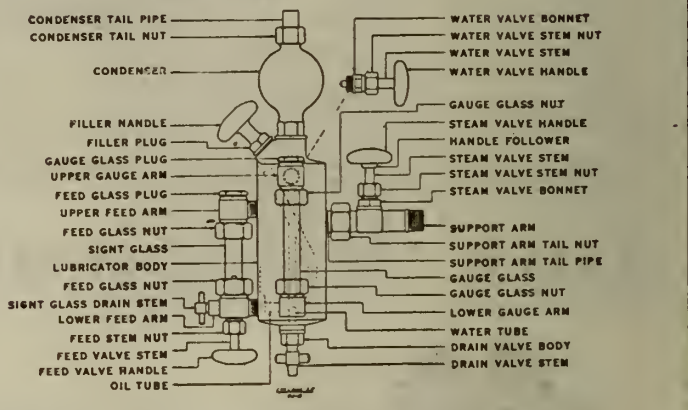
MICHIGAN
Cyclone Lubricators







The Michigan Cyclone Lubricator Keeps the Oil Warm

The distinctive feature of the Michigan Cyclone Lubricator is the large heating channel or caliduct which passes through the body from the support arm to the upper sight feed arm. This cored passage is a part of the original casting and in addition to its function as a heating chamber, it serves to strengthen the construction by binding and bracing the walls of the body. It will also be noticed that the main portion of this passage-way is considerably higher than the point of steam supply, thus making it self-draining and insuring that this heating chamber is always filled with live steam.

As the internal tube which delivers the oil to the lower sight feed arm rises within the body nearly as high as the filler opening, it will be seen that the oil is always fed from the upper portion of the body. In the Michigan Cyclone Lubricator the oil in the upper portion of the body is always kept in a heated and thoroughly liquid condition, by reason of this large, well designed, self draining heating chamber. Our Lubricators will, therefore, feed the heaviest oil freely and regularly, even in very cold weather.

Manufactured by

Michigan Lubricator Co.

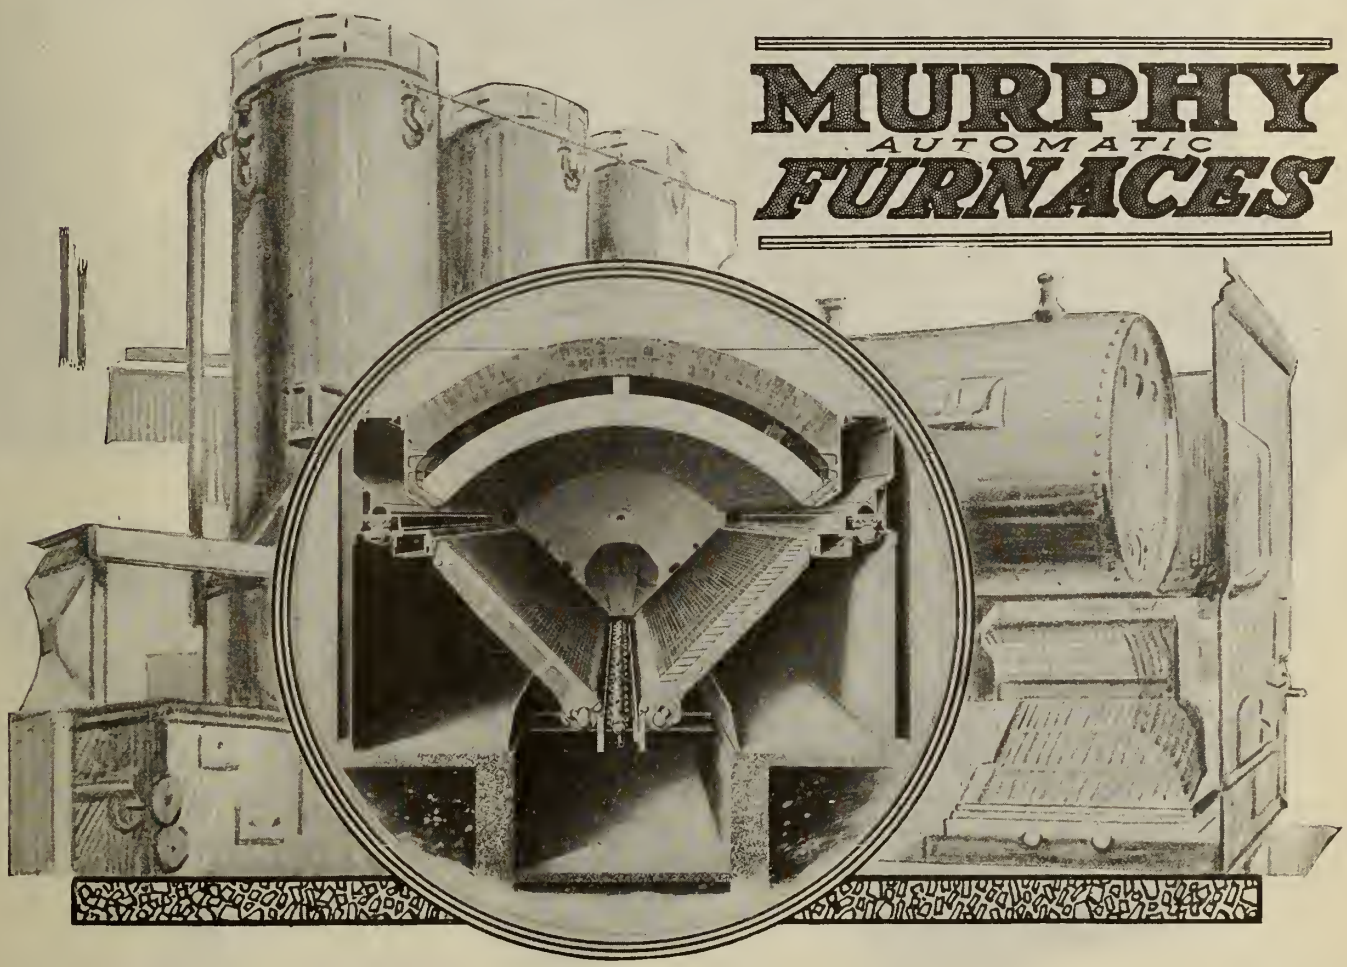
SOLD BY LEADING JOBBERS EVERYWHERE

For any type of Boiler



Any boiler from 50 H.P. and up can be equipped with the Murphy Furnace. The smaller plant can therefore enjoy all the economical advantages of the larger plant without resorting to forced draft.

The money you save on auxiliary equipment goes far toward paying for an installation of Murphy Furnaces.

Couple Natural Draft with Murphy ability to *burn any fuel that has heat in it* and you have a simple explanation of Murphy economy in hundreds—yes, thousands of plants.

If your boilers are 50 H.P. or larger you should write us. Catalog HM-10 places you under no obligation. Send for copy and see how easily the Murphy Furnace can be installed under any type of boiler.

STAY TIGHT *Permanently*

THE KEY TO SUCCESS

EXPERT KNOWLEDGE

OF THE PROCESS OF COMBUSTION AND BOILER ROOM MANAGEMENT is absolutely essential for success in the power plant engineering field today. The man that the big fellows are looking for is the man who, first of all, can utilize the last heat unit in the coal he burns under his boilers.

The Hays School of Combustion has provided the means by which this expert knowledge can be easily acquired by any one who will spend a few hours of his spare time to master the simple, interesting and easily understood lessons provided. The correspondence method of instruction is used, which permits any man to proceed according to the time available and his previous study of the subject. It teaches you all about the most up-to-date practice, all about fuels and how to obtain combustion efficiency, and all about boilers and furnaces and how to operate them economically. Every essential detail is supplied in this course, and in such a manner that you will find it more interesting than your favorite novel.

GREATER REWARDS

ARE WITHIN THE REACH OF THE COMPETENT COMBUSTION ENGINEER at the present time than in any other line of endeavor connected with the power plant field. Men who can select the proper kind of coal for each particular plant and condition, determine how it can be most efficiently burned, and, in the final analysis, **GET RESULTS**, with a minimum expenditure for fuel, are the fellows for whom the demand is, and will be, unlimited. If you want to be listed with the top-liners, this is your opportunity.

For the fireman, steam engineer, master mechanic or technical man, or for the young man seeking a lucrative calling, the sure job and the big pay, with all the accompanying advantages, there is no field so ripe—where the prospect of rapid advancement and quick returns is so promising. Employers are seeking greater efficiency in the operation, equipment and supervision of power plants. They want better trained men in the plants and more combustion engineers for consulting and construction work, giving opportunity for every grade of ability. If you have the foresight and ambition to train yourself, the opportunity is yours.

The course is written and arranged by Jos. W. Hays himself—in his well-known interesting and effective way of conveying the desired information. There is not a dull or uninteresting line in the whole course. The practical value of the course is unquestionably assured by the staff of Advisory and Reviewing Editors given below.

A Good Foundation For Your Choice

Are these fittings installed in your plant?

THE EMPIRE STEAM TRAP is made by The American District Steam Co., as are also the other fittings on this page. These traps are strictly a low pressure trap. The seamless electro-plated copper floats used are all tested to a pressure of 150 lbs. The trap has two inlets; one on either side, making it convenient for any piping arrangement. The automatic air valve operates by expansion, thereby preventing an air pocket.

DOUBLE EXPANSION JOINT

Expansion Joints for any Traverse and Pressure

THIS improved type of double expansion joint is especially suitable for underground steam pipe lines and is usually furnished with service or lateral opening and with anchorage as shown in the illustration. If desired, joints are furnished without anchorage, or service openings. All joints are thoroughly packed ready for use before shipment. Companion flanges, bolts and gaskets extra.

THE ST. JOHN STEAM METER

THIS meter indicates the amount of steam passing through it at any time and records on paper chart the amount of steam that has passed through during any given time. Made in sizes from 1 inch to 6 inches inclusive and for any pressure from 10 to 250 lbs. and superheat.

STEAM PIPE CASING

This Standard steam pipe casing is made from sound, thoroughly kiln-dried white pine, or cedar staves bound together with steel wire. Sections do not exceed 7½ ft. in length and are joined by means of mortise and tenon. Each section is given a thorough coating of pitch and sawdust, and the casing is lined with AAAA charcoal tin plate.

AMERICAN-MARSH PUMPS

SIMPLE RELIABLE EFFICIENT

The American-Marsh steam pump is an improved form of the famous Marsh Pump which has been on the market for over thirty years, during which time over 150,000 have been manufactured and sold.

The American-Marsh Pump has no internal stuffing boxes, no tappets and no slide valves. The auxiliary valve is of the semi-rotative disc type of an improved design. The main steam valve is of the balanced piston pattern, assuring highest efficiency. The water ends have large valve areas and are fully bronze fitted, including solid bronze piston rods and bronze removable water cylinder bushings.

American-Marsh Centrifugal Pumps are made with the same high grade of material and workmanship which characterizes the construction of the steam pumps. They are made in all sizes up to 12 inch, both single and two stage for heads up to 250 feet.

The line also includes—

Power Pumps
Deep Well Engines
Air Compressors
Jet Condensers
Dry Vacuum Pumps
Boiler Feed Pumps

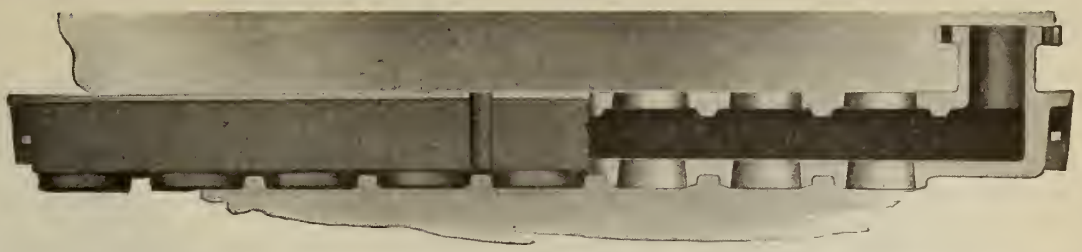
Top Headers



are constructed with tapered sockets to receive the tapered ends of the tubes. Directly above the sockets are hand holes used for inspecting, cleaning or removing damaged tubes. These hand holes are closed by internal lids, the construction of which is shown in right hand cut. The lids are passed inside the header, through a master lid hole and drawn into place by means of a yoke and key-bolt. They are then held in place by friction and by the water pressure inside the economizer.

The top headers are extended as shown so that the end tube may be cleaned or removed without disconnecting the branch pipe.

Why Lay Up Fire Brick Again —And have the same trouble year in and year out?

The ordinary brick lining with its joints gives way under the varying furnace temperatures, crumbles and falls down. With Betson's Plastic Fire Brick you can practically eliminate this maintenance of brick work.

BETSON'S REG. U.S. TRADE MARK PLASTIC FIRE BRICK PAT. OFF

is the pioneer and tried boiler refractory material, and has twenty years of practical experience behind it. Betson's takes up expansion and contraction internally. It is easy to lay up. It forms a monolithic lining without joints and there is nothing to work loose or fall down. It can be used for the entire boiler—furnace, door arches, rear arches, baffles, bridge walls, etc.

Let us quote you on Betson's Plastic Fire Brick for your boiler needs. Or send for our practical booklet to-day.

LUNKENHEIMER

Iron Body Bronze Mounted

Globe, Angle and Cross Valves

These valves give lasting satisfaction in service,—a fact vouched for by users everywhere. Their extreme strength and durability, due to high quality materials and correct design, is a source of economy in plant maintenance.

Lunkenheimer "Valve-iron" was formulated especially for valve service; it is close-grained, has high tensile strength and does not contain the excess of impurities common in ordinary grades of cast iron.

The trimmings are made of a high grade bronze, having exceptional wear-resisting qualities.

Constant checking of the mixtures by our laboratory division and careful tests and inspections before and after assembling, maintains the high standard by which Lunkenheimer valves are distinguished.

Specify LUNKENHEIMER and insist on having the genuine. Your local dealer can supply you; if not, write us.

MAPLE LEAF BRAND Stitched Cotton Duck BELTING

Made in Canada

Sets a standard in economy, strength and durability

It grips the pulley positively and is absolutely true running.

At a recent test Maple Leaf Brand Belting stood a breaking strain 50 per cent. greater than leather and 25 per cent. greater than rubber.

Costs less than leather, rubber or balata belting.

It's the best belting to use whether for transmission of power or conveying purposes.

Trying means convincing.

Republic Flow Meters

It takes fuel to produce steam—steam to produce power—power to produce every finished product. Steam is as worthy of consideration as any raw product—the amount produced is a check on fuel; the amount used is a check on power. Meter the output of boilers and you have a guide to firing and a means of detecting and correcting errors in boiler and settings. Meter the amount of steam consumed by power units and departments and you have a cost record that shows how much fuel goes into the finished product.

Three Main Sources of Fuel

The Indicating Instrument

The Integrating Instrument

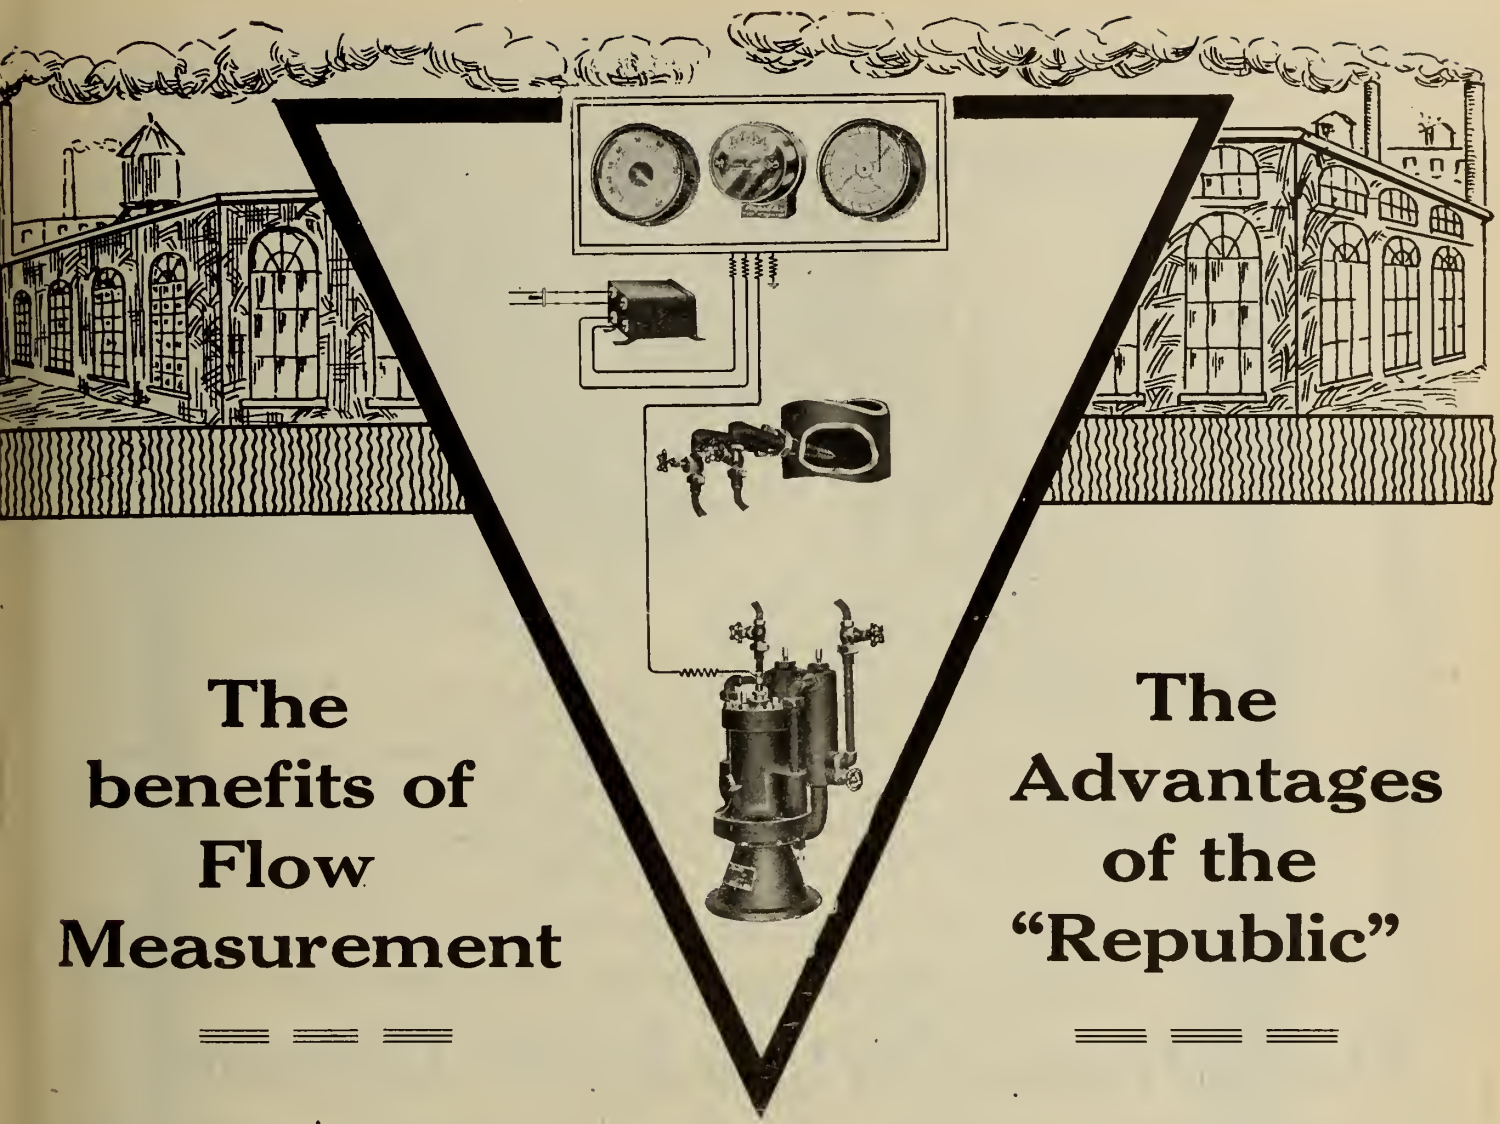
The Recording Instrument

Republic Flow Meters, by combining the known principle of fluid flow with electrical operation—an exclusive feature of the Republic — have made the measurements of steam flow universally practical in plants of every size, presenting every imaginable condition.

The reading instruments of Republic Flow Meters may be located any desired distance from the point of measurement—electrical operation makes this possible and insures greatest accuracy. Therefore, no matter how inaccessible the point of measurement or how many departments are to be metered in the most complicated system, Republic Meters indicate at a convenient, central point the three main conditions that enable you to prevent fuel waste.

Combustion efficiency is indirectly (but none the less effectively) indicated by the constant record of individual boiler output shown on the indicating instrument of the Republic Flow Meter. This Record is a constant guide to the fireman.

Republic Flow Meter Company,



The benefits of Flow Measurement

The Advantages of the "Republic"

Waste and their Prevention

Boiler efficiency is gauged by the graphic record and integrated total of output of individual boilers. Comparison of the records of different boilers is one of the most valuable aids in correcting errors in boilers and in determining the capacity at which highest efficiency with maximum fuel economy is attained. This comparison further permits properly dividing the load between different units.

Power costs are arrived at by consulting the reading instruments connected with meters attached to the steam line. The record of steam consumption by departments is particularly practical with the electrically operated Republic System.

Whether an elaborate system (as outlined above) is necessary in your plant, rests with your plant conditions. We will advise you as to the type of Republic System that will be of greatest value to you.

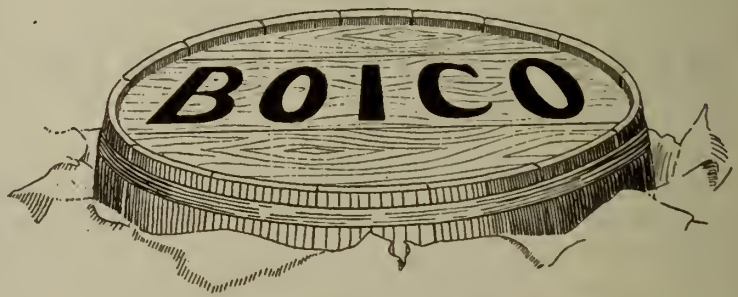
The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.** BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.



Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

Another Proof of Satisfaction

The reproduced letter from the Burroughs Adding Machine Co., Detroit, Mich., is self-explanatory. The DETROIT "V" TYPE STOKERS were installed in 1917 as part of the equipment used to determine whether power could be made for the factory cheaper than it could be bought.

The stokers ran true to their builders' claims as usual, and were instrumental in bearing out the engineer's predictions that the project was bound to succeed. That the Burroughs Adding Machine Company was satisfied is conclusively proven by the fact that a repeat order for Detroit Stokers for a new boiler has just been received.

Ask for the Bulletin.

Genuine British Oak-Tanned

LEATHER BELTING

The next time you buy belting, remember Oak Leaf—it will serve you as a guide to better belting service in your plant. There is no slip, it seldom requires tightening, and the expense common where ordinary belting is used, is reduced to a minimum.

D. K. McLaren's Leather Belting is made exclusively from close trimmed butts of the finest selected hides tanned by the old reliable British Oak Tanning Process. Many of Canada's largest plants are steady users, and a big percentage of our business consists of repeat orders, which speaks well for the popularity of the product.

If you wish to ask them how they like this belting, we will be glad to send you their names and addresses.

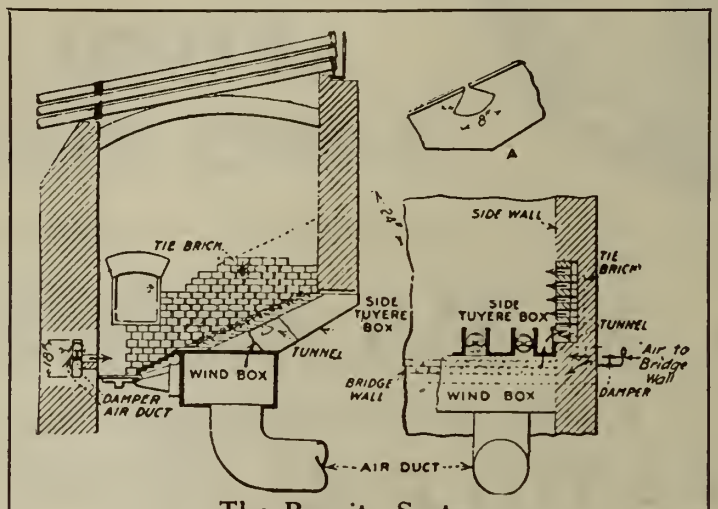
Add Power to Your Furnace

by eliminating the fuel-waste resulting from the "freezing" of clinkers to the side walls. The Bernitz Method of constructing side walls with interior air passages through which cooling air currents are passed to keep the bricks below the fusing point will

Positively Prevent the Accumulation of Clinker Mass.



The Bernitz System
as applied in a Taylor Stoker Installation

The Bernitz Method

1. Saves coal by insuring more perfect combustion of the fuel used.
2. Increases boiler efficiency by shortening time spent in cleaning walls.
3. Increases efficiency by burning coal which formerly clinkered.
4. By shortening time spent in cleaning walls reduces influx of air through doors.
5. Saves B.t.u.'s usually lost by radiation through side walls.
6. Permits increased forcing of fires by eliminating danger of clinker "freezing."
7. Makes it possible to remove such clinkers as are formed without dumping fire.
8. By reducing manual labor in boiler room keeps laborers more contented.
9. By keeping fires clean insures greater uniformity in heat applied.
10. Is equally applicable to old or new constructions.

The Bernitz Method is licensed, not sold. It has received full patent protection in Canada and in foreign countries and licenses under these patents are being granted on the basis of the H.P. rating of the boilers under which the Method is to be installed.

Mechanical Equipment of a Modern Dairy

The Dairy Business Has Developed Into a Branch of Applied Engineering Unique in Many Respects—This Article Describes Some of the Apparatus and Engineering Equipment Found in One of Modern Type.

By W. F. SUTHERLAND

THE milkman of former days with his measures and open can of milk has vanished from the streets of most of our cities, and rightly so. Milk is known as one of the best culture mediums for bacteria and other low forms of life dangerous to man so the distribution of milk in open containers was a constant invitation to disease. Contrast this with present day methods where milk is placed in cans, sterilized and sealed at the dairy, rushed to the city by motor truck and train and is finally delivered at the customer's door pasteurized and in sealed containers.

And in the handling of milk in the dairy, mechanical equipment is used throughout and, as may well be imagined, the power plant necessary for refrigeration purposes and for steam generation plays an important part. This article deals with some of the features of interest seen in the plant of the Farmers' Dairy Co., Ltd., at Toronto, Ont.

Since most of the equipment has to do with the direct handling of the milk, the various features of the plant will be described in order as they come into play.

Receiving

Conveyors save much human effort and expensive labor, and wherever possible are used in the present instances. As a result practically no lifting is needed from the time the milk enters the dairy in cans until it leaves bottled in the drivers' rigs.

Motor trucks are used for the collecting of milk cans from the farmers up to a radius of about 17 miles and are also used for the picking up of that part of the supply brought in by train. Standard sized cans are used, each one holding about 82½ lbs. of milk. These are loaded on a Mathews gravity conveyor and while passing to the weighing scales, have the seal, placed on by the farmer, removed and also his tag. When this is done one man empties them into a tank scale built by the Toledo Scale Co. And these scales automatically register the weight of the milk and a record is kept by the same attendant who removes the farmer's tag.

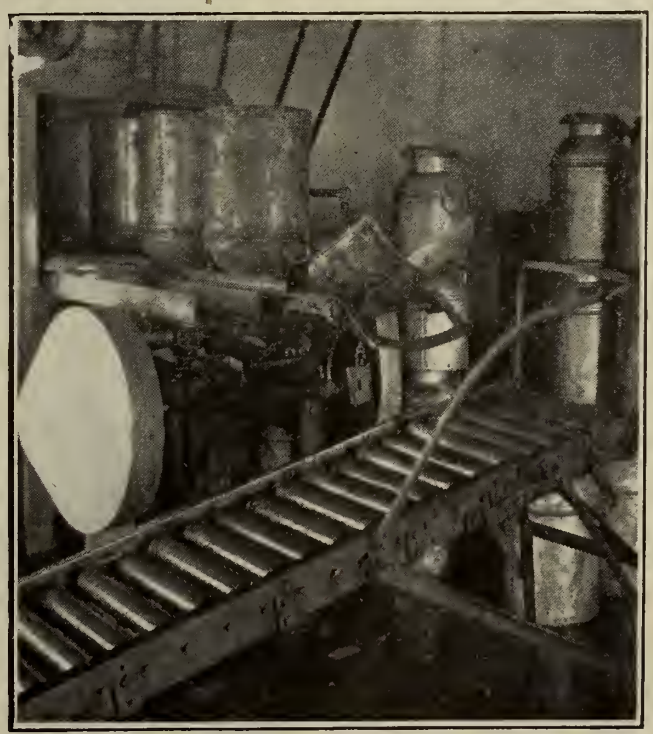

FIG. 1—CAN WASHER, DISCHARGE END SHOWING CAN TILTER AND CONVEYOR.

The cans, now empty, are placed on another conveyor, if it can be called such, for it is nothing but two pieces of flat iron set on edge with a pipe guard at each side. The milk dripping from the empty can furnishes the lubricant for easy sliding.

In an adjacent room, another attendant gives the can a bath outside and places it upon the travelling bed of a washing machine. The can is placed upside down and its cover also in the same position on another conveyor alongside.

Three water tanks are provided in this machine, the first supplying water at about 100° F., the second at 140° F., and the third at 180° F. The water is pumped from these tanks by three centrifugal pumps made by the Smart-Turner Machine Co., Hamilton, and having a capacity of 200 Imperial gallons per minute each. The discharge from these pumps terminates in nozzles under the travelling conveyor on which the cans and their covers are placed and the hot water is forced into them under a head of 40 ft. Since the cans travel only intermittently, each one is subjected to the three streams of hot water for an interval. After being washed they stop over a jet of live steam where they are sterilized and then over a blast of hot air supplied by a blower and heating coils. This thoroughly dries them inside and they emerge from the washer.

The ordinary milk can has a recessed bottom and this collects some water while the can goes through the washing machine. To get rid of this, an ingenious device has been rigged up which automatically tips the can, throwing the water out and up-ends it into a short conveyor, from which it is removed, sealed and returned to the farmer.

The centrifugal pumps, blower and an exhauster for the

removal of steam are driven by a 7½ h.p. motor. Each pump has a thermometer on the discharge side and the temperature is kept constant by a steam jet in each tank. Make up water to the amount of about 2 gallons per minute is supplied by the hot water system in the boiler room and soda is used in the first tank to cut the dirt.

Returning to the milk which we left in the scales; after weighing, it is run out into a second tank at a lower level, from which it is pumped to the pasteurizing room, two floors above, or into milk storage tanks on the next floor. The pump which performs this work has some features of in-

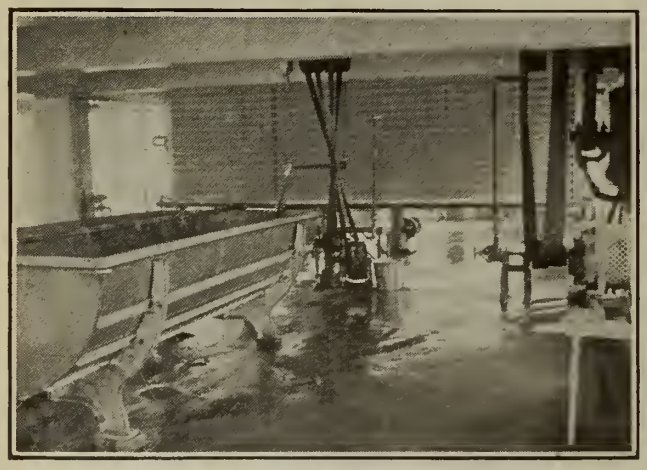

FIG. 2—MILK PREHEATER.

terest. The steam end is standard but the milk end is entirely of brass and so arranged that it can be entirely dismantled in a few minutes for cleaning. This is done every night, and throughout the plant, all piping handling milk, is so arranged with unions and caps that it can be taken down, washed with hot water and sterilized with steam. The piping evidently is of heavy copper, tinned inside and out, and the fittings are of brass, heavily nickeled. The milk pump above described is made by O. H. Burrell and Co., Little Falls, N. Y.

The bulk milk storage room contains three copper tanks heavily tinned which hold 160 cans each. All have agitators to keep the cream from rising to the top. A one and one-half horsepower motor drives the agitators through worm gears and also a brass gear pump, which delivers the milk from the tanks to the pasteurizing room above. The milk storage room is cork insulated with refrigerator doors and is maintained at a temperature of 40° Fah. by means of the cold air system which will be described under the power plant.

Pasteurizing Room

The milk from the weigh scales or the storage tanks, as the case may be, is received in a receiving vat shown in the illustration and holding 50 cans. This has also an agitator driven by worm gear from a line shaft. In passing, it may be mentioned that the plant layout throughout, is so designed as to keep the milk in constant circulation, no chance being given for the cream to separate.

From this receiving vat the milk is pumped over a preheater shown in the illustration. This preheater consists of sixteen 3-in. copper tubes, 14 ft. long, arranged in a vertical stack and divided into two sections with heavy brass headers. The milk flows from a distributing trough on top to a receiving trough below, and is raised in temperature from 40° Fah. to 120°. Water is used as a heating medium and on entering is at a temperature of about 140°. About 50 gallons per minute are required. This quantity is variable, depending on temperature conditions and is controlled by hand. The preheater works on the counter flow principle, that is the hottest water meets the hottest milk.

The pump used in pumping the milk from the vat to the preheater is quite novel in construction, and, like the other pumps handling milk, permits of ready dismantling. No valves are used, but the flow of milk is produced by a combined reciprocating and rotative motion of the piston about its axis, the piston being shaped so that it uncovers the suction and discharge ports at the proper part of the stroke. To effect this motion of the piston, the piston rod is coupled to the crank disc by a ball and socket construction, the crank shaft being set perpendicular to the piston rod, which continues on past it to a bottom guide.

After having been preheated the milk is filtered through special filter cotton and then flows to the pasteurizers, of which there are five. These hold fifty cans of milk each. The milk, while being heated in them, is kept constantly in motion by means of a copper worm driven through gears and belt from a line shaft below. This worm also serves another purpose, that of heating, for by its revolving motion it draws in hot water from a tank on the end of the pasteurizer, circulates it in the copper worm and discharges it at the other end, from whence it returns into the tank again. The water is maintained at the proper temperature of 170 deg. Fahr. by a small steam jet. In these pasteurizers the milk is held at 142 deg. Fahr. for 30 minutes, during which time all bacteria, etc., are killed. The hot water overflow from the tanks is returned to the basement tank of the plant hot water system. Tycos recording thermometers are installed on each pasteurizer.

The copper coils in the pasteurizers are also used for another purpose, that of cooling the milk after pasteurizing. Cold water circulated through them brings the milk down to 130 deg. Fahr. before discharge. Much trouble was experienced in finding a suitable packing for the stuffing boxes on the ends of the worm shaft, through which the water flows in and out of the pasteurizer. A flax and rubber packing is now used and no trouble is encountered.

From the pasteurizers the milk flows by gravity to the coolers, of which there are two, situated one-half floor below the pasteurizer room. Each cooler consists of twenty-four 2½ in. copper tubes heavily tinned inside and out. The milk flows over the outside and city water is taken through the top sixteen, the lower eight tubes being brine cooled. The water passes into the tubes at the bottom, emerging at the top, so that the coolest

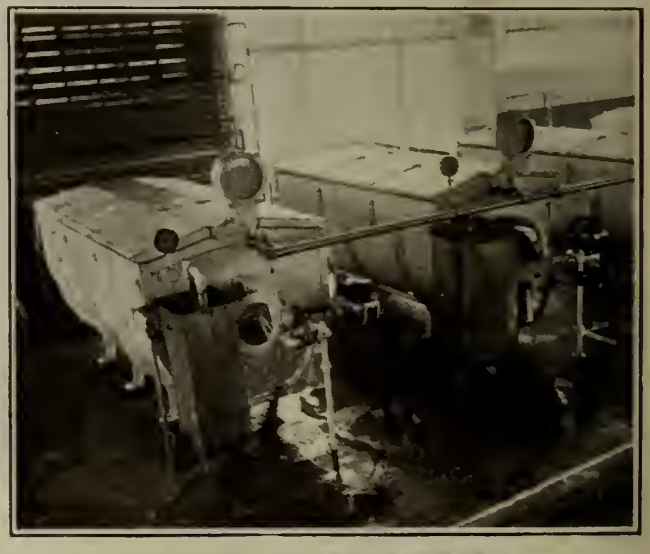

FIG. 3—TWO OF THE PASTEURIZERS.

water is adjacent to the coolest milk. These coolers can handle easily 74,250 lbs. of milk in eight hours.

The flow over the coolers is intermittent and is controlled by an automatic hydraulic regulator devised by Mr. Cairns. Fig 5 shows a diagrammatic view of the arrangement. A copper float is located in the milk

receivers at the bottom of one of the coolers and is attached to a ¼-in. ball-cock. This ball-cock is connected to a ¼-in. pipe line connected in turn to the city water service through a ¼-in. pet-cock and gauge. When the milk rises to a predetermined level, the float rises and

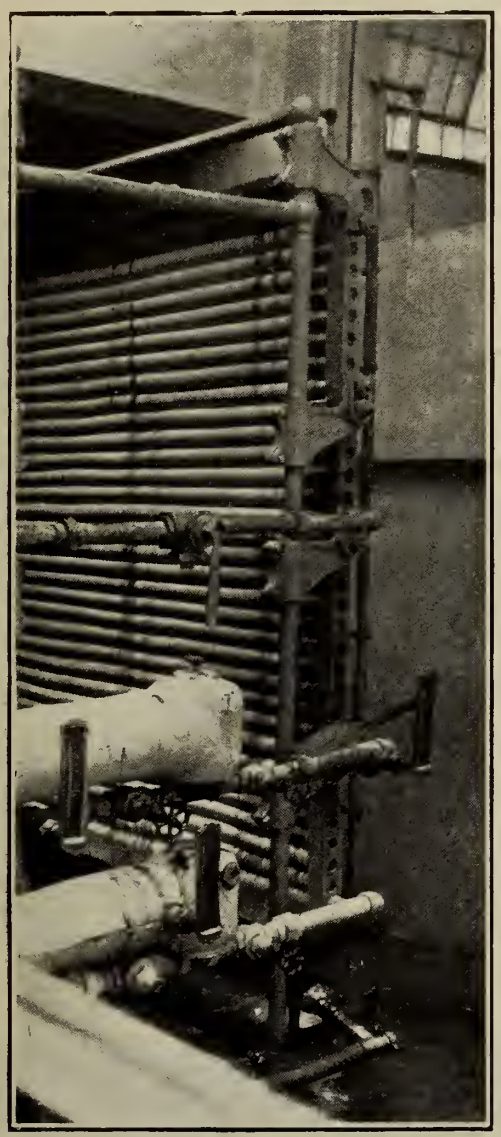

FIG. 4—ONE SECTION OF MILK COOLER.

allows the ball-cock to open, letting the water run to waste. As the water wasted is greater in amount than is supplied to the system by the pet-cock from the city water system the pressure drops. The pressure in the regulating system actuates two hydraulic plungers of 1 and 3 in. strokes. These plungers operate valves which control the flow of cooling water through the cooler and also the flow of milk over it. When the milk level rises the ball-cock is opened and the pressure falls, the weights pulling the valve-operating links down, thus closing both valves. When the milk level drops the reverse action takes place and the water and milk valves open.

The water valve is an ordinary whistle valve, while that on the milk feed is of somewhat unusual construction. By reference to Fig. 5 it will be seen to consist of a cross capped at the lower end and terminating at the top in an open copper pipe. The inside of the tee, which is of brass, is smooth and inside it travels a short piece of copper tubing, which forms the valve. This tube is connected to a piece of ¼-in. brass pipe, which in turn is connected to the lever and hydraulic cylinder. The copper tube is long enough to reach above the level of the milk in the pasteurizers and thus no packing is required. The cap on the bottom of the cross is easily removable and the milk flowing through the valve eddies down into this recess, thus sweeping out any stagnant milk.

The hydraulic cylinders are adjusted for one-inch travel and the pistons are packed with two leather cups, which have proved entirely satisfactory.

The coolers serve to reduce the temperature of the milk from 120 deg. to 32 deg. F., and from them the milk flows to the bottling machines on the floor below. These machines will fill any sized bottle, from the small cream bottles to a one-quart milk bottle. The bottles are placed in the machines by the attendants and pass to the filling nozzles or valves, where they are elevated and filled. The larger sizes are filled in stages and air is vented through a small tube, which passes through the milk above. The bottles are finally capped and are placed in crates and go to the milk storage room. The Universal filling machines have a capacity of 45 bottles of milk per minute each and are each driven by a ¾ h.p. motor through a chain drive.

Skim Milk

While on the subject of milk and cream it may be well to mention what is done with skim milk. The disposal of this has been a matter of speculation to the writer for some time, and at last his curiosity is appeased. Formerly it was allowed to run to waste, but it is now poured into a vat in the basement, and a certain amount of sulphuric acid is added. This precipitates the casein which is filtered and pressed free from whey, dried, powdered and sacked for shipment to other firms. These take it and use it in the making of buttons, billiard balls, milady's ivory toilet articles, etc.

A churn room also forms a portion of the equipment with milk conditioners, two one thousand pound churns and separators, etc. This equipment is shown in Fig. 8.

A laboratory is also necessary for milk testing. Dirt, bacteria and acidity must all be closely checked if good milk is to be sold at all times.

Prohibition and Buttermilk

The bottled milk, together with milk pasteurized, cooled and placed in milk cans for restaurants and the wholesale trade is kept in a large milk storage room, ready for the drivers. The temperature of this room is maintained at about 40 deg. Fahr. by means of the cold air system to be described later. In this room also, but-

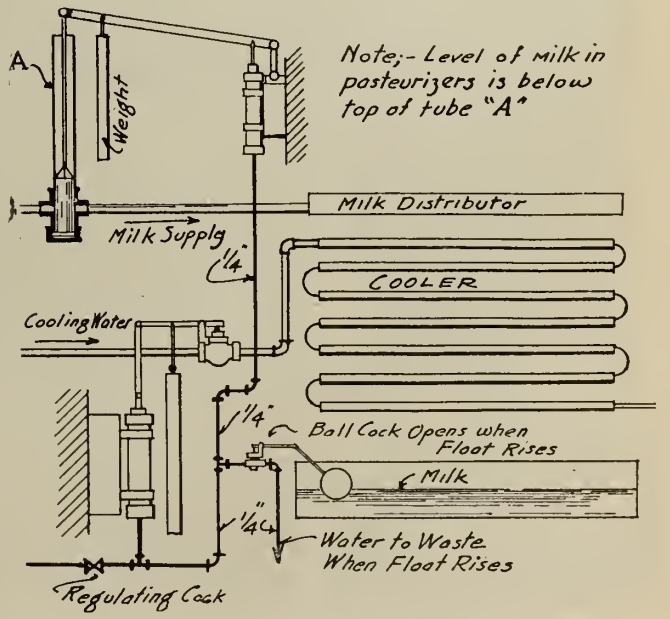

FIG. 5—DIAGRAM OF AUTOMATIC CONTROL FOR MILK AND WATER FLOW TO COOLER.

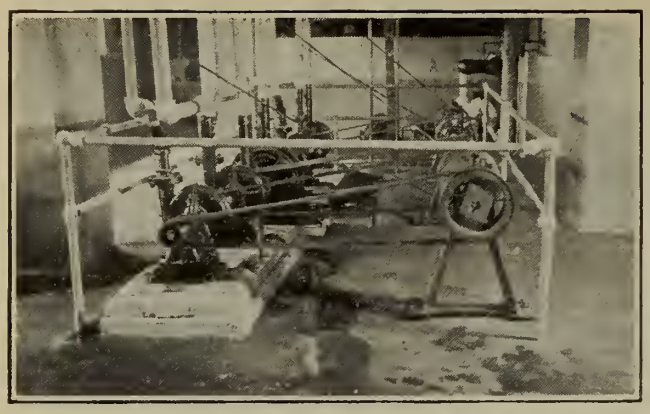

FIG. 6—PUMPS FOR BOTTLE WASHER.

termilk is bottled and placed in cans. It is a noticeable fact that sales of this beverage have increased very materially since the stuff with a kick to it can no longer be had unless by ways dark and devious.

Drivers receive their supplies through small doors opening onto a loading platform, in which are short lengths of Mathews gravity conveyor.

On their return they unload the empty bottles in cases onto another conveyor, which carries them into the bottle wash-room. The bottle washer, in some respects, resembles the can washer described above, consisting as it does of an intermittently travelling conveyor above plates containing wash water nozzles. The cases of empty bottles are turned upside down on an iron frame, placed on a rack and shoved into the machine by a pusher. The track consists of rollers at the sides and interference with the water jets is obviated.

Four tanks, each holding about 75 gal. of water, are located underneath the washer and four centrifugal pumps downstairs in the basement force 250 gals. of water each under 35 ft. head through 3-16-in. nozzles, one for each bottle. The bottles stop over each station, of which there are eight, two for each tank. These thoroughly clean the inside of the bottle, while three other sprays wash the outside. The first tank contains water, which is lukewarm; the second water at about 110 deg. Fahr.; the third at 140 deg. Fahr.; and the last at boiling point. The proper temperature is maintained in each by means of steam jets. Make-up water flows into the hottest tank at about 4 gallons per minute and equalizing pipes are arranged between the tanks, the overflow, together with the scum and dirt, flowing away to the sewer.

Emerging from the washer the bottles are turned right side up by an attendant and placed on a gravity carrier, which takes them to the filling room. This conveyor is fed by a pusher mechanism similar to that used for the washing machine. While on this conveyor the bottles pass over a duct, through which cool air is blown, passing up and around the bottles. This cools and also dries them, ready for filling.

Pumps For Bottle Washer

Perhaps the most interesting feature of this bottle-washer is the battery of pumps located in the basement and shown in Fig. 6. Four Goulds' centrifugal pumps each deliver 200 imperial gallons per minute against a pressure of about 30 lbs. The four are belt-driven from a shaft by a 25 h.p., 3-phase, 25-cycle motor, which, from the same shaft, also drives the automatic pusher mechanism or feeders for the washer and conveyor above. The shaft hangers are bolted to the floor and are of the S K F ball bearing type. Beardmore waterproof leather belting is used.

Refrigeration

The refrigerating system may be divided into two parts, one which supplies cold brine to the milk coolers, etc., and the other which supplies cold air to the bottled milk storage and to the milk storage room.

Two 8-ton Brunswick compressors are installed for the brine system. These are of the twin cylinder, vertical, hot gas type, the cylinders being water jacketed.

The Brunswick Manufacturing Co., New Brunswick, N.J., use a number of novel features in the construction of these machines. The necessary reciprocating motion of the pistons is secured not by cranks, but by eccentrics, through which the shaft passes. These eccentrics are of cast iron and the eccentric straps are also of the same material. The wrist pin and eccentric strap are all one piece and the eccentric is made with a projecting hub which runs in the bearings. Thus all the shaft has to do

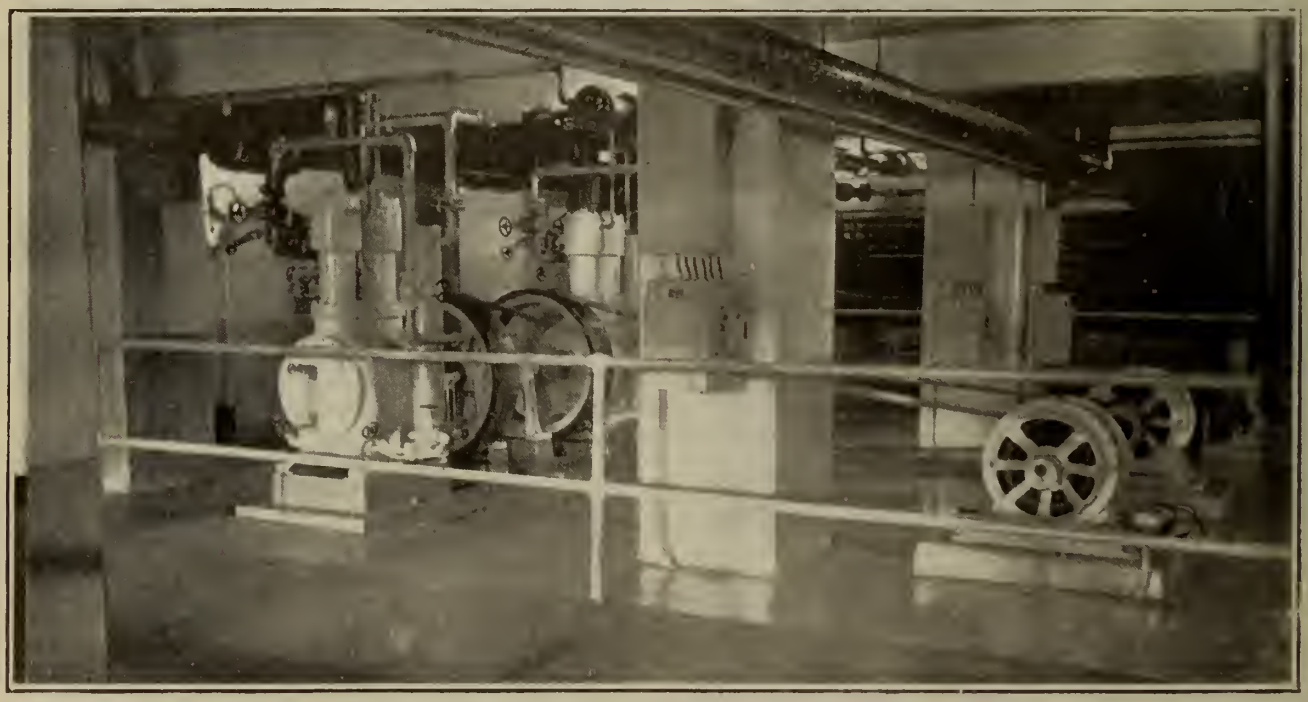

FIG. 8 TWO OF THE AMMONIA COMPRESSORS AND THEIR DRIVING MOTORS, TOGETHER WITH STARTING COMPENSATORS ON COLUMNS.

is to transmit the necessary turning torque and is relieved to a large extent of bearing stresses.

An oil collector is placed on the discharge side of the compressors to collect any oil entrained in the gas. The oil is returned to the crank case, which is enclosed.

Another feature of interest is seen in the outboard bearing. Contrary to usual practice, the shaft runs in a cast iron sleeve, and while this at first sight might be expected to lead to trouble, none has been experienced.

Each of the two 8-ton machines is driven by an 8-in. Beardmore heavy, single-ply, waterproof leather belt from a 15 h.p. Lincoln motor. This installation is seen to advantage in Figs. 8 and 9.

For the supplying of cold air to the milk storage rooms a 12-ton compressor of the same make and type is provided. This machine is driven by a 25 h.p. motor, a 10-in. double-ply belt being used.

Brine System

Two Smart-Turner centrifugal brine pumps, each of 75 gal. per min. capacity, circulate the brine from the brine tank to the milk coolers above. These pumps have a 5 h.p. motor belted to each. Two brine tanks are provided with a total capacity of 700 cu. ft. These are insulated by Armstrong cork. One tank has three sections of double pipe brine cooler submerged in the brine ,while the other one contains two. The return line of the brine circulating system comes back through the double pipe brine cooler, in at the bottom and out at the top, discharging into the body of the tank, which acts as a storage. The discharge and return lines of the brine system are cross-connected through a relief valve, so that any excess discharge over that required by the milk coolers is taken care of.

Blast Room and Cold Air System

The blast room, which supplies cold air to the bottled milk storage and to the reserve milk rooms, contains four stacks of direct expansion coils, containing 3,600 ft. of 2-in. pipe. Air is taken in from the top of the milk storage rooms by a Sheldon fan driven by a 3 h.p. motor and is discharged into the blast room. The air is delivered across the coils, which have a set of three heavy galvanized baffle plates and returns to the storage rooms through ducts in the hollow tile walls, being delivered near the floor on the opposite side from which it was taken away. The blast room is 26 ft. by 10 ft. in size

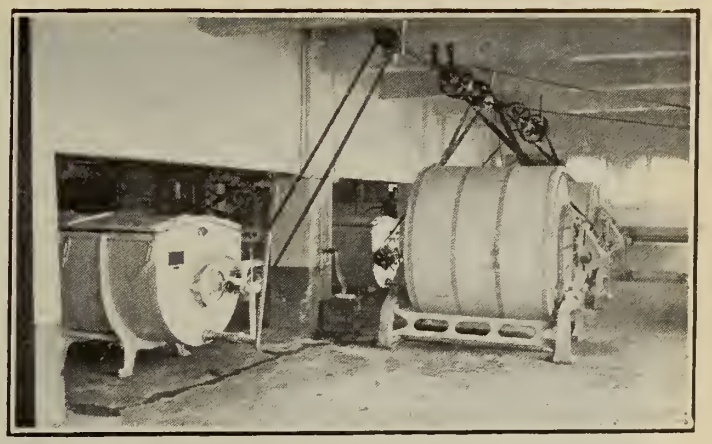

FIG. 7—CHURN ROOM SHOWING MILK CONDITIONER AND CHURNS.

and the walls are built up of 4 in. Armstrong cork, plastered inside and out. The fan and air ducts are insulated with felt covered by canvas and painted.

Outside air is used for cooling purposes during the colder months of the year, being taken in through an opening to the outside in the suction line to the fan.

The storage rooms contain a total of 25,000 cubic feet of space and the walls are constructed of hollow tile with 2 in. of Armstrong cork insulation on both sides, plastered over with cement plaster.

All doors to the blast room and storage rooms were supplied by the Jamison Cold Storage Door Co., Hagerstown, Md.

A small Smart-Turner pump, driven by a direct connected one h.p. motor, serves to remove condensed moisture from the blast room and for emergency use a Penberthy water ejector is also provided.

The ammonia condenser is of double pipe counter flow type and of Brunswick make. Ammonia enters at the top and the water at the bottom, the condensed ammonia flowing out at the bottom into a receiver. The condenser is three stacks wide, each stack being eleven pipes high. The inner pipes carrying the cooling water are 1¼ in. dia., while the outer ones are 2 in. The condenser is 18 ft. long. City water is used for cooling. The exhaust from the small steam-driven milk pump upstairs on

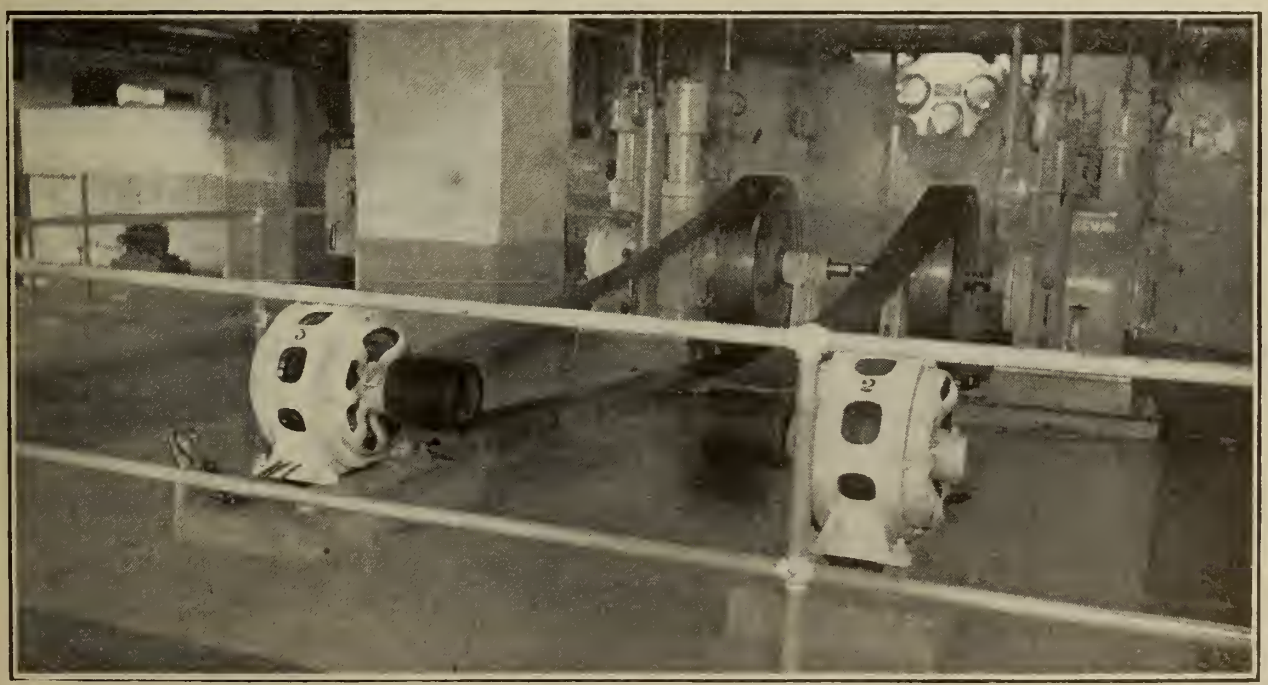

FIG. 9—MOTOR DRIVE FOR AMMONIA COMPRESSORS.

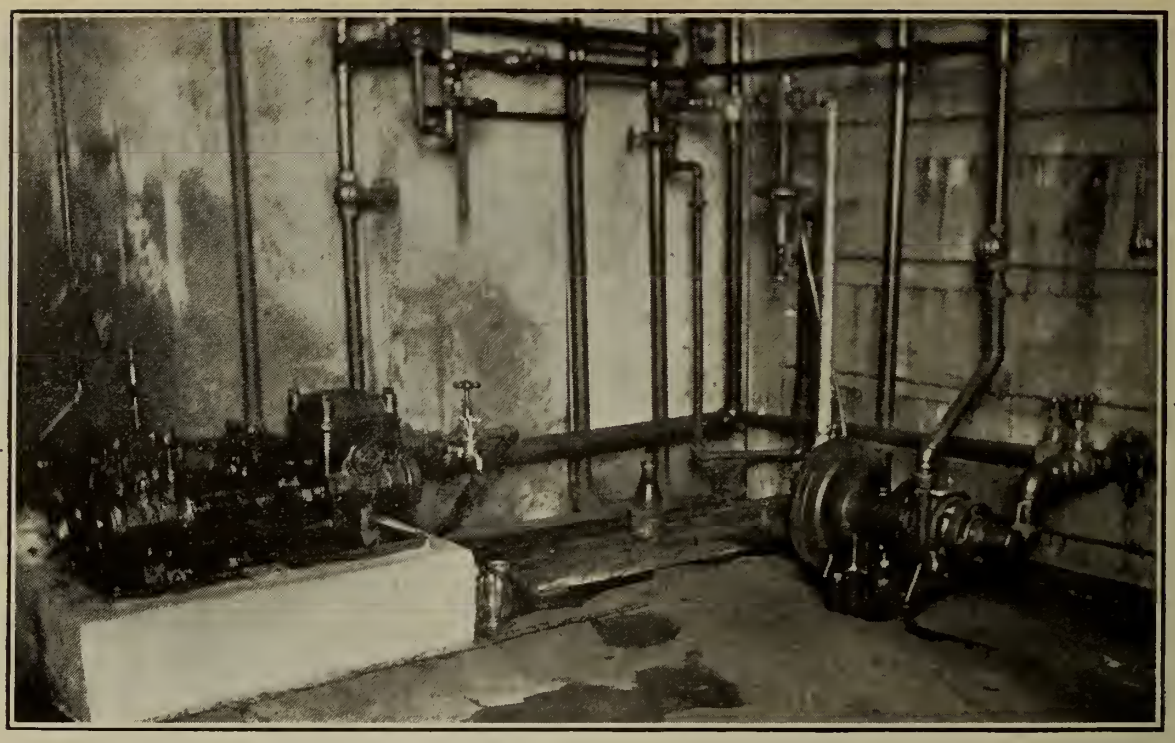

FIG. 10—COPPUS FEED WATER PUMP AND TANK.

account of its intermittent character and oily nature is of no use, and so is turned into the discharge line from the condenser, where it is condensed and carried away to the sewer.

Expansion Header

The liquid line from the receiver is led to an expansion header at a spot conveniently near to both the brine and blast room expansion coils. Here nine leads are taken off, five for the brine system and four for the blast room. Next to the welded steel header on each line is placed an ammonia valve and immediately above them the expansion valves proper. When these latter have been properly adjusted they are never touched, any cutting out or in of sections of the expansion coils being done by the ammonia valves.

Extra heavy pipe is used throughout on the ammonia system and scale traps are provided at each compressor and at the expansion header. Armstrong cork insulation is used on all liquid lines and returns to the compressors as well as on the brine circulating system.

The compressors on the brine system and the blast room are ordinarily run separately, but provision is made for cross-connecting when necessary.

The jacket water from the ammonia compressors is led to one of the columns and runs to waste through sight feed flows, one for each compressor mounted on it.

Boiler Room

For heating purposes during the winter months and for supplying the large quantities of steam and hot water necessary for plant operation, two 50 horsepower Jenckes return tabular boilers are installed. These boilers have individual settings and are fitted with Cyclone shaking grates. For overload conditions and also for use when the natural draft is poor, due to a hill back of the plant, Coppus undergrate blowers are fitted.

The main stop valve to each boiler is of Jenkins make, and 3½-in. Lunkenheimer non-return valves are also fitted. The steam header is dripped at three places in its length, the two drips in the boiler room being taken care of by an Anderson trap, while the third one at the far end of the basement is also fitted with a trap of the same make.

Four different methods of feeding the boilers are available, city water pressure, a Penberthy injector, a 4½ x 2¾ x 4 in. Smart-Turner duplex pump and a Coppus turbine-driven feed pump. The latter is in regular use, the other apparatus being maintained for stand-by service.

The tank from which the boiler is fed and from which other plant requirements for hot water are met is of cypress, 3 in. thick and 7 ft. by 8 ft. by 6 ft. high, holding 2,083 gallons. The boiler feed pump suction line has a vertical riser terminating in a funnel at the top higher in level than the water in the tank. This is used for feeding boiler compound when required. No regular compound is used for a soda preparation. "Wyandotte," made by the Ford Co. Wyandotte, has been found to answer the purpose quite satisfactorily. This material is in common use for laundry and dairy purposes.

The Coppus pump is operated against a head of 100 lbs. and is of sufficient size to feed 1,000 boiler horsepower, the excess delivery over that required by the boilers going to supply other plant requirements. A Mason excess pressure regulator set at 110 lb. and in-

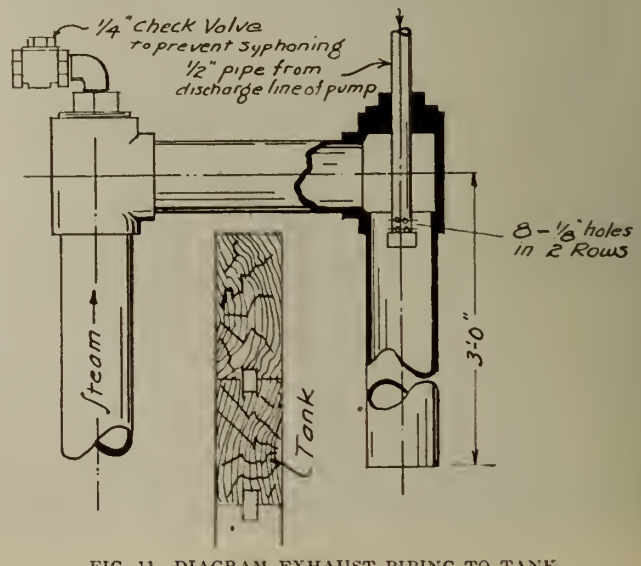

FIG. 11—DIAGRAM EXHAUST PIPING TO TANK

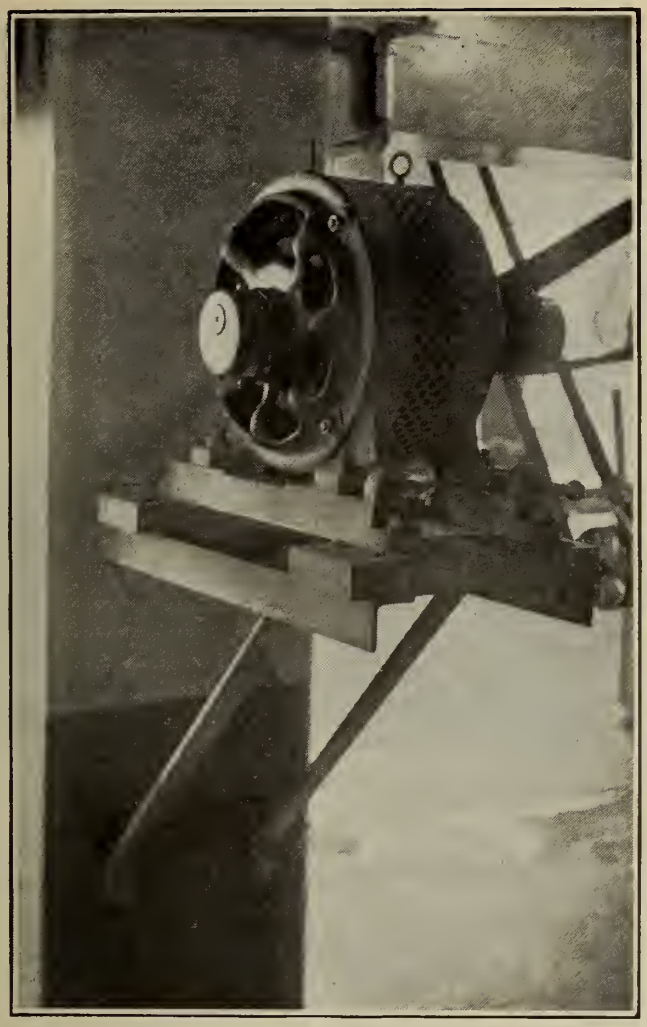

FIG. 12—MOTOR BRACKET ON CONCRETE COLUMN.

stalled on the steam line controls the speed of the pump and thus its delivery.

The pump drawing its supply from the hot water tank delivers water at 140 deg. Fahr. to the boiler, lavatory service, make-up for can and bottle washing machines and also forty gallons per min. to the milk preheater. The water which goes to the preheater returns to the tank and the overflow water from the pasteurizers is also recovered. The make-up water supply is drawn from the ammonia condenser cooling water waste.

Exhaust steam from the Coppus pump is used to heat the water in the tank. Fig. 11 shows the arrangement of the exhaust piping. The exhaust terminates 3 ft. below water level and a tee is installed at the top. In this tee a one-half inch pipe has been inserted, capped at its lower end and drilled with eight one-eighth in. holes immediately above the cap. The one-half inch line takes water from the discharge line of the pump and this water injected under pressure serves to condense the steam and prevents disagreeable noise so common when steam is introduced into a body of water. The other tee shown in the figure has a one-quarter inch check valve opening inwards attached. This serves to break any vacuum formed when the turbine is shut down.

The correct water level is maintained by the boiler room attendant and he is warned of the need for replenishment by steam blowing into the boiler-room, quite a simple low water alarm. The tank being below sewer level a connection is made from the discharge line to the sewer for the emptying of the tank when necessary.

The Dunham system, installed under the supervision of the C. A. Dunham Co., is used throughout the main dairy building and the stables some distance away. Steam at boiler pressure of 90 lb. is reduced to the proper pressure by Fisher reducing valves, and the 4x4x8 in. Bawden vacuum pump is controlled by a Fisher regulator. The condensate from the heating system is returned to the hot water tank, while the exhaust steam from the vacuum pump and the duplex feed pump passes through an oil separator into the heating system.

A Turnbull hydraulic lift is used for hoisting ashes to street level. Carey's insulation is used throughout on steam lines.

The steam fitting, plumbing and heating were installed by A. Welch and Sons, Toronto. The dairy apparatus and refrigeration were installed by the W. A. Drummond Co., Toronto. The packing used on all ammonia flanges is Garlock No. 900, a hydraulically compressed asbestos packing. Practically all motors, some twenty-two in number, are of three-phase, 25-cycle, 550-volt type, made by the Lincoln Electric Co., Toronto.

Organization

The Farmers' Dairy Co., Ltd., is an organization composed entirely of milk producers, no one having any financial interest in the company except farmers. Milk is received principally from the shareholders, although some is obtained from other sources. Started ten years ago, the industry has shown a remarkable growth. At the start, less than 1,000 lbs. of milk was distributed per day, and at the present time a quantity of approximately 100,000 lbs. is handled in the same time. The present plant is, of course, a gradual development through the en-year period, and further extensions are contemplated. Mr. Robert Cairns is mechanical superintendent.

Fly-wheel Explosion

ON August 15th the fly-wheel of a 250-h.p. Filer and Stowell Corliss engine in the Sattley Building, Racine, Wis., exploded with a terrific crash, demolishing a large part of the building, killing one man and injuring three others. The building, which houses a number of manufacturing concerns, rocked as if an earthquake had struck it and the employees scattered in all directions.

The cause of the accident was evidently a deranged governor as the engine attained a terrific speed before the wheel let go. Herman Kobal, assistant engineer, was seated directly behind the wheel and when the engine began to race and the generators began to throw their windings he started to get out. He had just got outside when the wheel let go and a piece came through the wall and struck him, killing him instantly.

The cylinder dimensions of the engines was 22 by 44 in., it operated at 90 r.p.m. and 125-lb. steam pressure, and was installed 14 years ago. The fly-wheel was 14 ft. in diameter with a 26-in. face and weighed 8 tons. Belted to this was a 200-kw. d.-c. 125-volt generator and one 150-kw. a.-c. 220-volt generator with revolving fields.

Pieces of the wheel went into the Wallis Tractor Factory, tore a hole through a 12-in. wall and then struck the machine at which William Dedrichs was working. His machine was wrecked and he had to be taken to a hospital. A post 12 in. in diameter was splintered into fragments so small that not a piece of wood was left larger than half an inch. The damage is estimated at $35,000.

One piece weighing more than a ton went about five hundred feet in the air, and landed in the yard of a foundry company which is 350 ft. from place where it started from. Another piece crashed through a six-inch brick wall and going in a southerly direction landed on top of a tractor some distance away. The tractor was badly wrecked and the same piece also took off part of an overhead runway in its flight.

The generators are a total loss as the windings on the armature of the d.-c. machine was thrown out completely and the frame cracked. The revolving field of the alternator left the spider and the frame on this machine was also cracked.—*The National Engineer.*

Auxiliary Apparatus of the Steam Power Plant

The Modern Power Plant Has Many Accessories Not Dreamed of by the Engineer of a Few Years Back—These Articles Will Review and Illustrate the Various Types of Auxiliaries

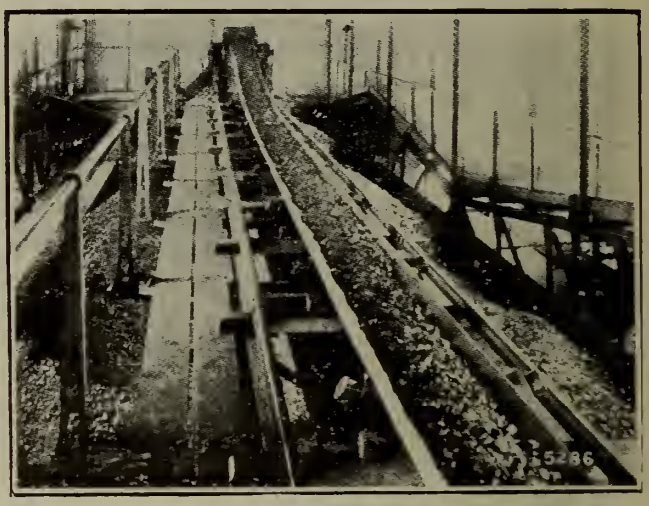
By T. H. FENNER, Associate Editor

AUXILIARY appliances cover a very wide field in the modern industrial power plant, and it is sometimes a moot point as to what can be classified under this head. From the writer's point of view, any machinery or appliance apart from the main boilers and engines can rightly be called auxiliary machinery.

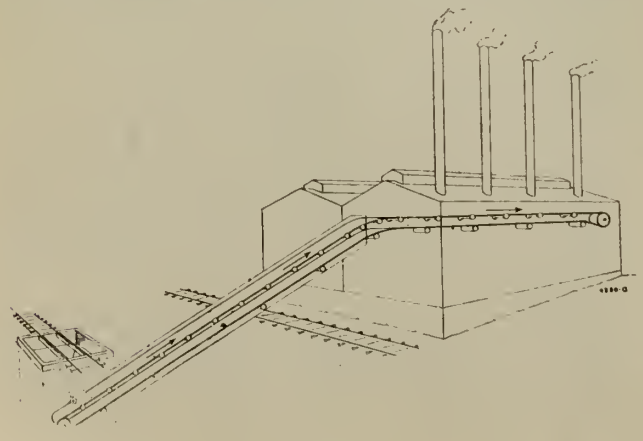
The engineer who possesses a broad knowledge of the various types of auxiliaries and accessories, and their applications to a particular problem, is in a position to make his advice valued. If to this knowledge he adds a grasp of the commercial possibilities and can show where a comparatively large outlay can justify itself to the owner or manager, he will have no trouble in introducing economical improvements into his plant.

It may be conceded at once that practically every piece of auxiliary apparatus on the market has some point of merit, otherwise it could not survive. Generally, when any of the better known makes of traps, pumps, injectors, fans, or whatever it is, falls down on the job, the fault is not with the machine, but the treatment it receives. Too often, in going through a power plant, one sees an expensive piece of machinery standing forlorn and idle. Enquiry elicits the information that "It's no —— use, and never was." Probably the next day one sees the identical appliance functioning in a most efficient manner in a similar plant and under similar conditions to those seen the previous day. Obviously the fault is not with the machine.

Another handicap which auxiliary machinery too often suffers under is that due to pure cussedness of human nature. For instance, if a piece of machinery is bought and installed when the chief engineer has set his heart on a different make, the chances of the installation making good are very poor. Again, an engineer may install a certain auxiliary, and leave the plant. The man who follows him may favor another make, and will too frequently try to make the one installed prove his contention that it's no good. Of course, this is not universal, but there is enough of it occurring to cause trouble. An instance along these lines, although not exactly concerned with auxiliary machinery, occurs to my memory. A certain type of watchman's flash light, which was operated by a storage battery, or rather storage cell, contained in an aluminum case, was purchased for the night watchmen's use. These batteries could be charged during the day and would burn continuously for about 12 hours. As they were only used about 3 hours each night, this left an ample margin. However, before the lights were purchased the head watchman had heard a man with some authority in the plant say they were no good. The head watchman always made a point of being in agreement with this particular person, so the word went out to all the watchmen that the lamps were no good. The result was they weren't. The watchmen finally refused to use them, and they were returned to the power house store. Those lamps were as good an article for the purpose as could be found, but they didn't get a chance. The mistake, of course, was in the management not insisting on their use even if it involved the dismissal of the watchmen. However, it goes to show what prejudice can do to an article.

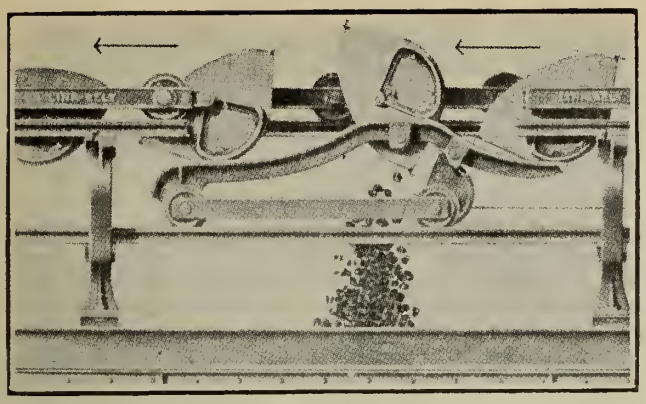


BELT CONVEYOR IN BUNKER LINK BELT COMPANY.



BELT CONVEYOR FROM OUTSIDE STORAGE LINK BELT CO.

A lot of equipment that a comparatively short time ago was looked upon as a luxury, yet only for the large and expensive plant is now acknowledged to be a necessity for economical working. It is not a great many years ago that the average stationary engineer looked upon CO_2 indicators, recording thermometers, feed water meters, etc., as being very pretty, but of little real value. This view is being very rapidly changed, and there are few engineers who would refuse to install any of these instruments if they had the chance. At the same time, increasing power costs have made plant managers more eager to invest in instruments and machines for increasing the efficiency of operation. High-priced and hard to obtain common labor has led to the much wider adoption of mechanical coal and ash-handling machinery. The mechanical stoker, which can burn with success a low grade coal, is coming more and more into use. Fans and turbine blowers have also become a necessity where cheaper grade coals have to be burnt. Where the size of the plants warrants it, economizers are being installed in the uptakes. Feed water heating apparatus, various types of return traps for handling condensation, vacuum pumps in connection with heating systems are almost universal. Manufacturing processes have necessitated the introduction of special machinery in the power house, outside of the main units, such as air compressors and high pressure hydraulic pumps and accumulators. Water filtration systems and chlorinating appliances for drinking water are also in evidence in some cases. Central lubricating oil pumps, supplying lubricating and cylinder oil to all the units in the plant are another refinement.



SHOWING METHOD OF UNLOADING PIVOTED BUCKET.

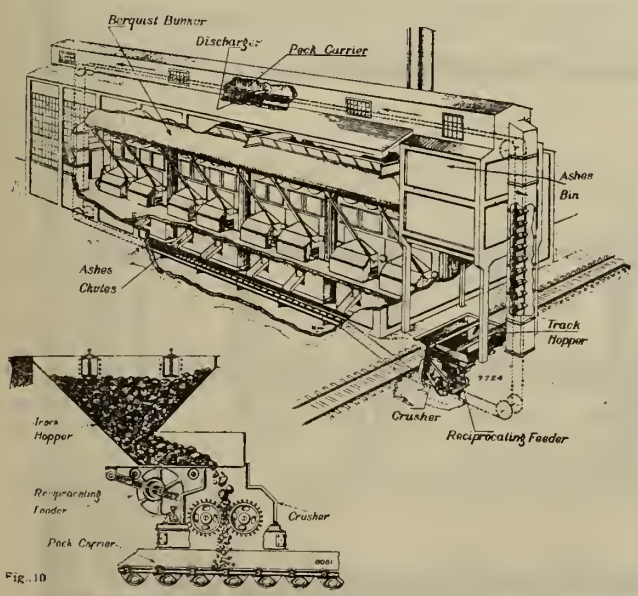
The absolutely necessary appliances, such as feed pumps, and condenser circulating pumps are, of course, always with us, while various types of feed regulators, high and low water alarms, are found in steadily increasing numbers.

Coal and Ash Handling

The logical place to start the consideration of a steam power plant is in the boiler room, and as the initial source of power is the coal, handling the coal is the first thing we shall consider.

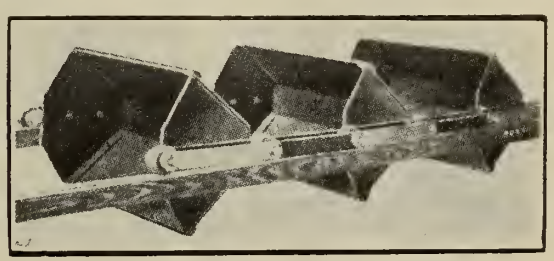
There are in this country more of the one boiler type of plant than any other. These plants employ perhaps one man, who looks after boiler and engine, and in some cases two men, an engineer and fireman. As many of these small plants handle fuel other than coal, such as sawdust, shavings, tan bark, etc., the problem of economical handling does not enter. In the plants of this size burning coal, the small amount of coal burned does not justify the installation of machinery to handle it. In some cases, for instance, where boilers are situated in the basement of a building, the ashes have to be elevated to the street level. If it is an office building, the usual plan is to use an ordinary elevator, of the hydraulic plunger type, which also serves the building in general. There may be a small bucket and chain elevator, dumping into the cart drawn up in the street outside, or in some cases, the most primitive appliance of all, a pair of blocks, and hand-power to elevate the ash bucket.

The handling of ashes is often a question in small and medium-sized plants, where the coal handling practically takes care of itself. This can be readily understood. The coal in most cases can be drawn to the bunker or directly



BOILER HOUSE WITH PECK CARRIER AND OVERHEAD BINS.

in front of the boiler and dumped within easy reach of the fireman. On the other hand, the disposal of the ashes often means the transporting of them a comparatively long distance from the boiler room. In a small plant, the cost of this handling by hand labor may easily be very high in comparison to other power costs, while the coal-handling cost is but small. A cheap and efficient arrangement in a case of this kind is the ordinary I-beam and electric trolley. The writer is personally acquainted with several plants where this arrangement is in use. One in particular is a good example. The boilers are of the vertical type, 28 feet high over all, the boiler and engine room being some ten feet below the street level. Coal is brought into the yard in carts, which simply dump into the bunker, which opens into the boiler room. For bringing the coal to the boiler front, a four-wheel truck, on ball bearings, is employed. This truck holds a known quantity of coal, so that it forms an accurate means of measuring by simply keeping a tally. The side of the truck is hinged, allowing it to drop down, which makes it partially self-unloading. For handling the ashes, a bucket is used which runs on rollers and fits under the fire door. It is large enough to contain all the ashes pulled when cleaning fires. About 16 feet above the floor level the I-beam is installed, and this runs across the boiler room and out into the yard. A Sprague Electric Company travelling trolley of 1 ton capacity runs on the beam and is controlled from the floor by means of wires attached



GRAVITY CONVEYOR BUCKETS.

to the switches. There are four controls altogether, hoisting, lowering and travelling either way. The man on the floor hoists the bucket of ashes, and runs it to the door, when the man in the yard, usually the carter, takes charge of it and places it in position over the cart. The bucket is pivoted below its centre of gravity, and the opening of a catch allows it to dump. This makes a very convenient and cheap arrangement of low first cost, and little expense for upkeep. The same plan, with modifications to suit local conditions, is in use in many plants, and for the small concern, is hard to beat.

When we consider coal handling, the first question to be considered is that of storage. If the plant is so situated that coal can be obtained daily by cart from a local dealer, a large space for storage is not required. On the other hand, if coal is brought in direct by rail, or boat, storage is an absolute necessity. No plant can expect to receive coal regularly by rail, especially in the winter, and in the case of coal coming in by boat, it is usual to procure sufficient supply in the summer to carry on through the winter.

In the case of the small plant, such as was just mentioned, storage facilities would not be more than sufficient for two or three days. Even when the storage bin was nearly empty the coal would be comparatively close to the boiler room, and the amount of handling required not much greater. However, when the necessity of storing quantities of 1,000 tons and over exists, the question of moving this coal becomes an expensive one. The wheeling of coal in barrows from bins to boiler room is not only expensive in labor, but is wasteful in coal. There is always a certain amount being lost by spilling from barrows, and being trod into dust on the floor, especially with the smaller types of coal. If in addition the ashes

are handled by being pulled out of the fire onto the boiler-room floor, there is an almost certain further loss by coal going out with the ashes.

In the ideal installation the coal should never be touched by hand from the time it arrives in the yard by train till it is delivered as ash into the car again. In some large stations this condition is practically fulfilled, but in the smaller plants the cost of the necessary equipment can not always be justified. However, there are few plants where some form of mechanical handling cannot be introduced to advantage.

It is usual to arrange, where coal is delivered by rail, for the cars to run up on a trestle and dump their contents into the bin below. When the coal is in gondola cars this involves practically no work in the car itself, but trimming is necessary in the bin. This is the first handling. If the car is a box car, some shovelling will be necessary in unloading. After the coal is trimmed into the bin it must be wheeled from there and deposited in front of each firing door. After the coal is burned the remaining ash must be removed from the fire, and wheeled out of the boiler-room, a more or less distance.

Suppose we have a plant of four H.R.T. boilers, rated at 125 h.p. each, or 500 h.p. total. This plant would require two firemen and one trimmer during the day, and during the winter months a trimmer would be necessary at night. During the working day about 20,000 lbs. coal would be burnt, and according to the quality of coal about 2,000 to 4,000 pounds of ashes would be handled. If the plant is closed down at night there will be only one man needed in the boiler-room to keep steam handy, and have everything ready for starting up in the morning. For three months of the year a trimmer will also be necessary on account of the heating proposition. If now equipment can be installed to eliminate the trimmer during the day and the night trimmer during the winter months, a saving of, roughly, $20 per week all the year round, and $40 a week for three months can be made. This would amount to $1,250 a year. A saving of this much justifies an investment of $6,000 to $8,000. This amount in a plant of this size would supply a full mechanical equipment, which would effect a larger saving than that estimated.

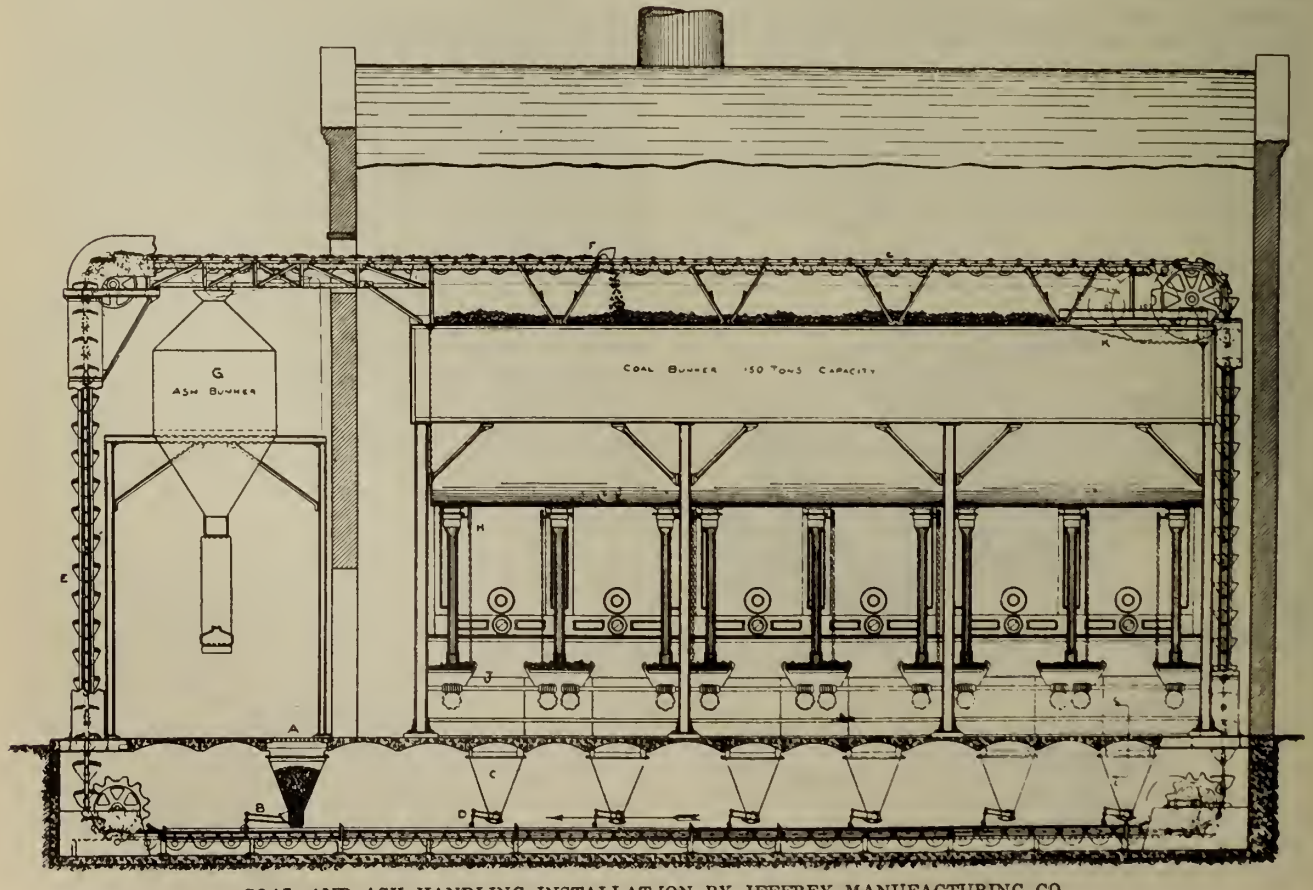
The chief means adopted for handling coal automatically is by elevators of the belt, bucket, or flight type, while the ash-handling is effected by bucket elevator, spiral conveyor, suction, or pneumatic elevators. Some of these will be described in this article.

The Belt Conveyor

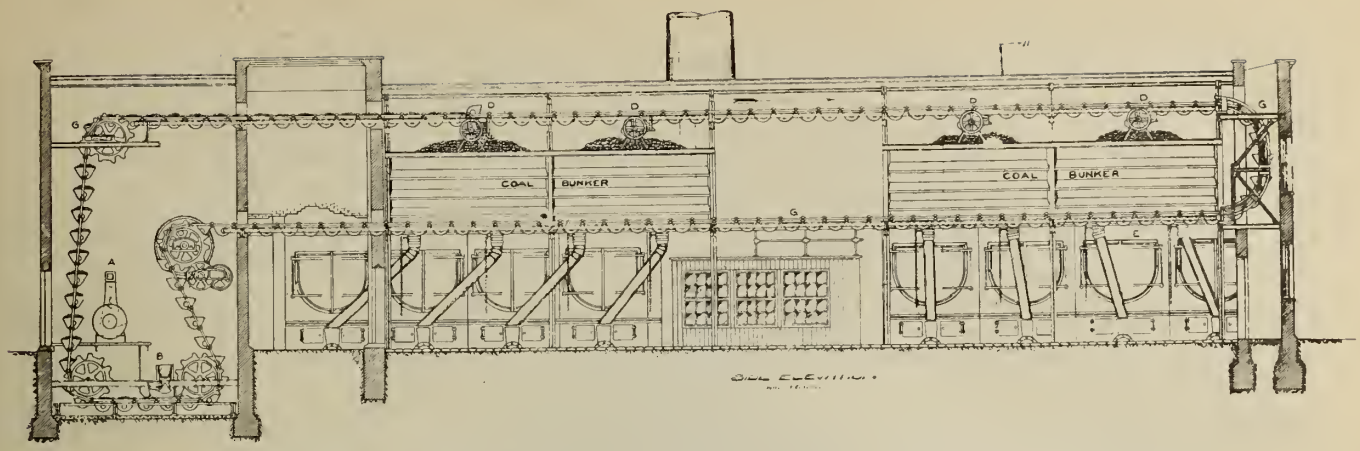
The belt conveyor consists essentially of a broad rubber belt, travelling over rollers. The coal is carried in bulk on the surface of the belt. The guiding rollers are usually arranged in groups of three, the centre one being horizontal, while the two side ones are inclined at an angle of from 15 deg. to 30 deg. This keeps the contents from spilling over the edge of the belt while in transit. For conveying coal long distances, as from an outside storage to a bin in the boiler room, this type of conveyor is very suitable. It will deliver to an overhead bin where the distance is sufficiently long to allow the elevation to take place at a slight incline. Obviously, this type of conveyor cannot be used where the inclination would be higher than the natural angle of repose of the coal. Owing to the cost of the material, this type of conveyor is rather high in first cost, but maintenance should not be very high, and the capacity is greater in proportion than a flight or bucket conveyor, owing to the continuity of carrying surface. We show typical cases in our illustrations, which are obtained through the courtesy of the Link Belt Co., Chicago. The coal is discharged from the belt at any desired point by a tripper, which can be moved along to the spot required. The tripper consists of two pulleys, so arranged that the belt passes over one and back around the other, the effect being the same as if the belt ended at that spot.

Gravity Discharge and Bucket Types

The greater part of the elevator and conveyor equipment for coal is of the above type. Fundamentally ,the principle of the gravity discharge and bucket elevator is the same. Containers are spaced at even distances along



COAL AND ASH HANDLING INSTALLATION BY JEFFREY MANUFACTURING CO.



INSTALLATION AT HIRAM WALKER DISTILLERY—JEFFREY MANUFACTURING COMPANY.

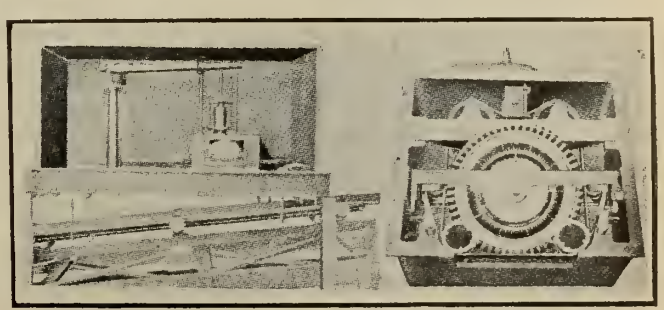
an endless chain, which is carried on horizontal tracks and vertical guides, so as to be capable of both elevating and distributing the coal over a space governed by the distance apart of the vertical legs. The chain is composed of flat steel bars, secured to chilled iron or steel rollers. The containers are secured to the links, either rigidly or on a pivoted bearing. Here lies the chief difference between the gravity discharge and the bucket elevator. The containers on the bucket elevator hang always vertically, and must be tipped by some outside agency before they will discharge. The containers on the gravity discharge type are rigidly secured to the links in such a way that when the chain is ascending the bucket will be vertical, thus holding its contents. As the chain runs over the top guide pulleys, and starts its horizontal run, the buckets turn with the chain in such a manner as to dump their contents. To distribute the coal at desired points a sheet steel upper run is constructed, with gates at certain distances, which can be opened by suitable means from the boiler-room floor. The power for driving is usually furnished by a small motor, and this is always set at the top of the elevator leg. The motor drives direct through spur gears to the main driving sprockets of the elevator.

The problem usually is to bring the coal from the cars to storage, and also to deliver from storage to boilers. The particular plan adopted will depend on the nature of the building and storage. Supposing the plant is one where the cars can deliver the coal directly into an inside storage. The problem then is to distribute the coal in the storage and to the boilers. To do this, a flight conveyor is used in conjunction with a bucket or gravity elevator conveyor. The flight conveyor is a form of scraper, the flights or drags, of malleable iron, being secured at distances of about twelve to eighteen inches apart, on an endless chain. The cars discharge into a hopper, which delivers the coal onto the flight conveyor, this in turn delivering to the boot of the bucket or gravity discharge elevator. The coal is then elevated to the desired height, and discharged either into an overhead bin, or direct to spouts leading either into the stoker hoppers or onto the boiler-room floor. Alternatively it may be discharged back into the building storage to be reclaimed as necessary. To do this, the lower run is encased in a tunnel, and placed a little below the floor level of the storage. Quick acting gates are placed at frequent intervals along the tunnel, which can be operated from the inside. The coal flows through these gates by gravity into the conveyor, and is then carried up to the delivery spouts. In the case of the storage being of necessity outside the building, it may be delivered to an overhead bin by means of a belt, as previously stated, or by a locomotive crane delivering to the hopper used for the cars. Another plan is to build an overhead rail, and use a small electric hoist and grab bucket to carry the coal to the overhead bin in the boiler room. Sometimes the overhead bin is built outside at the end of the boiler-room, and the coal carried in and distributed by an electric hopper direct to the stoker spouts. We show several illustrations of various arrangements of conveyors.

As one of the principal points in handling coal is to know how much of it is being used, some form of weighing machinery is necessary. A track scale to weigh the coal as it is delivered is a very good means of making sure receiving what is paid for. That of itself is not enough. It is important that the coal being delivered to each boiler should be known, so that a check on the performance of each unit can be kept. This can be done by suitable weighing machines connected with the delivery spout from the conveyor, or situated at some point where two conveyors cross. Most of these scales are automatic in their action, and are very reliable. In the writer's opinion, the scale should always be included in the conveyor plant, as the slight extra cost involved is well worth while. The correct weighing of coal delivered to a boiler is very difficult without some special means of this kind. The type used is generally one with two hoppers, containing a known quantity of coal. When the top hopper is filled, the feed is shut off, and a gate opens automatically, allowing the coal to feed into the lower hopper. This is also fitted with a gate, which can open only if the outlet is free underneath. If not, it holds the coal until the space underneath is cleared, when it dumps. An automatic counter is fitted which records the number of times the hopper empties itself. Other machines are made for weighing the coal as it passes over the conveyor, and contain an integrating device to count the number of pounds passing over. The illustration shows one type of these scales. The method adopted is to hang a short section of the conveyor on rods connected with the beam of the scale. This section is balanced by an iron float in a cylinder of mercury. The movement of this float affords a direct measurement of the varying weights passing over the floating section, and then the speed at which the conveyor is running must be taken into account. The integrating device does this.

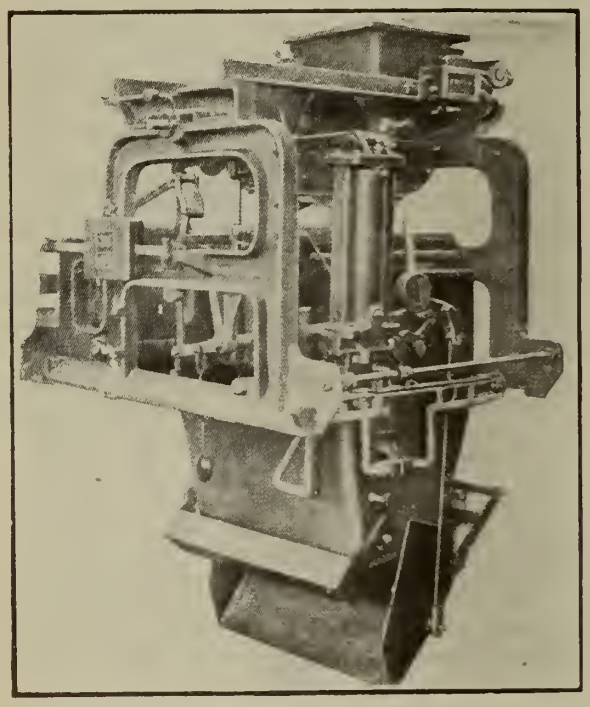
Ash Handling

The handling of ashes, when performed by hand labor,



WEIGHING MACHINE ON CONVEYOR.

is one of the most unpleasant and costly jobs about the plant. Machinery that dispenses with the necessity of this labor is a double blessing. Besides the conveyor systems used for coal, a different type altogether is employed for ashes. In marine work an ejector worked by a blast of steam is used, but in land practice, a steam jet is used to cause a vacuum in a pipe, and the ashes are drawn through by atmospheric pressure. In some plants the coal-handling conveyor is also used for ashes, the lower run of the conveyor being used for this purpose. In others a special conveyor is used to handle ashes alone. The ashes are usually taken from a pit under the boiler, and elevated to a storage bin, from which they can be loaded into the cars direct. In other cases, no storage is provided, space being valuable, and the ashes are elevated directly into the cars. Some installations have in use a spiral screw in a shallow pit directly under the fire doors, and the ashes are raked out of the fire onto a grating, through which they feed onto the screw conveyor. This pushes them along into the boot of an elevator. Where mechanical stoking is used, particularly of the chain grate type, the ashes drop over the back end of the grate, and roll down an incline to the conveyor. Belts are naturally of no use for this work, the nature of the material handled being too destructive. Owing to the wetness of the ashes and their corrosive action, cast or malleable iron make the best resisting material for the conveyor. The flight conveyor can be used for removing the ashes from the boiler front to the elevator leg.



AUTOMATIC COAL WEIGHING HOPPER.

In installing ash conveying machinery it is necessary to consider whether the ashes have to be removed at the moment of cleaning fires, or if they can be allowed to accumulate during the day and be removed at night only. If the coal-handling machinery is fully occupied during the day in supplying the coal, but is idle during the night, arrangements for storing the ashes during the day and removing them by the coal-handling machinery at night is most economical. Sometimes the coal conveyor is more than ample to handle the load during the day, and can be utilized for ash-handling at intervals. If the plant works day and night, fully employing the coal-handling machinery, separate means for dealing with the ashes must be installed. It is impossible to lay down any definite rule for determining the type of installation. Every plant must be considered on its own conditions, and the various factors of first cost, maintenance, etc., taken into account. There are cases where an installation of mechanical equipment is justified, even when it will show a very small actual saving. In plants where labor is difficult to obtain and hard to keep, due to local conditions, mechanical equipment will ofttimes be the means of ensuring continuity of operation. Smooth-running and freedom from annoying stoppages in the power plant are worth money to the production end, and in this way money invested in boiler-room equipment gives a return in dollars and cents.

Before installing mechanical coal and ash-handling machinery, the problem should be put up to the makers of this equipment. Their wide knowledge and experience of different installations make them very well qualified to advise the plant owner, and to assist the plant engineer in the choice of the most suitable equipment.

ELECTRIC TOOL TEMPERING

Successful attempts have been made to employ an electric tool tempering furnace in the Westinghouse Works. The barium-chloride and salt principle is utilized and the furnace consists of an outer shell, a cast iron cylinder packed with fire bricks and an occasional layer of asbestos. The heat is supplied by two pairs of electrodes built in on opposite sides of the walls of the inner chamber. The electrodes operate on a 16 to 30 volt alternating current circuit. After starting up salt is fed into the furnace, which on melting completes the circuit, and a mixture of barium-chloride is then fed in. It has been found in practice that there is great ease of control of the heat and that good work can be performed at a comparatively low cost of operation.

FROM A CALF'S DIARY	FROM A DITTO DIARY
Kicked over my pail of mash.	Kicked for half an hour about my job.
Got my head caught in a bucket.	Got my head full of thoughts of how undervalued I am.
Yelled like blazes for mother for an hour.	Yelled like blazes at everybody who didn't please me.
Rolled my eyes at a little boy and frightened him.	Rolled a cigarette so as to have it ready for the first opportunity to get a few puffs at it.
Experimented on how far I could spraddle my legs.	Experimented on how far I could go doing nothing and get away with it.
Tangled myself in ten feet of rope.	Tangled myself in mental trash.
Nibbled at a small green apple and had a tummy ache.	Nibbled at a small green apple and added a disordered stomach to my other disqualifications.
Refused to be hugged by an impudent hired man.	Refused to be mindful of all the comfortable conditions under which a man works in these times.

Mechanical Features of an Office Building

Oil Fuel and Complete Equipment Make Power Plant Unusually Interesting to Engineers

The Welfare of Office Employees Has Been Well Taken Care Of.

By W. F. SUTHERLAND

THE modern type of office building erected to-day for the use of industrial firms and business men has little in common with those formerly built. Aside from the excellent working conditions with which the occupant is surrounded a greater degree of interest in his or her physical well being or comfort is manifest. One of the most excellent examples of this type of office building is that of the Imperial Oil Co., on Church St., Toronto, where a gymnasium, a squash court, shower baths, etc., have been incorporated into the building design for those who wish to use them. The mechanical features of this plant are also of more than passing interest to the engineer, for it is seldom that a power plant reflects the attention to detail appearance seen in the present instance.

Heating Plant

Heating is done by a combination of direct radiation and the plenum system. Direct radiation is used for all the main offices, while for basement rooms, squash court, gymnasium, etc, etc., and for the lavatories warm air is supplied by air washing and heating apparatus of the usual type made by the Carrier Air Conditioning Co. of America, 39 Cortlandt St., New York. The usual tempering coils, air washer baffles and main heating coils are fitted and the fan is driven by a 5 h.p. Sprague variable speed motor. The spray pump is driven by a smaller 2.5 h.p. Peerless Motor. Fresh air is drawn in from the roof through a fresh air duct and after being humidified and warmed is distributed throughout the building where required by a plenum chamber and the usual air ducts.

The air temperature is regulated by automatic temperature controlling apparatus made by the Power Regulator Co., New York. Thermostats are located on the incoming cold air side of the tempering coils and also on the outgoing side of the main heating coils. These serve to control the temperature through remote controlled valves on the main steam lines. A uniform temperature is thus secured at all times, no matter what the condition of the air outside.

As mentioned above direct radiation is employed for the heating of the main offices, etc. The Dunham vacuum sysem, installed under the direction of the C. A. Dunham Co., Ltd., Toronto, is used and the excellent arrangement of the piping vacuum and feed pumps, together with the Fisher regulators, will be seen from Fig. 2. Two Blake and Knowles vacuum pumps are employed, each being fitted with a Fisher regulator as shown. These pumps are 8 x 8 x 12 in size and discharge into a hot water receiver above the feed pumps. This receiver is fitted with a float actuating the steam valves on the feed pumps so that they are only running when there is water in the receiver. When the receiver is empty the pumps automatically cut off. The feed pumps, of which there are two, are of the Worthington duplex type, 5½ x 3 x 5 in. in size.

Boilers

For the supplying of steam to the heating system and also to take care of the future power load if an isolated plant is ever thought desirable, two Heine boilers of 195 B. H. P. each are installed in a double setting. These boilers are fitted with circulating blow-offs, etc., and the breeching is carried over to a steel stack 3 ft. 6 in. diameter, which is carried to the roof in a brick well. The pressure carried at present is 65 lbs. with provision made for an increase to 125 lbs. when power is generated in the future. This pressure is reduced to a proper value by means of a Fisher reducing valve.

The boilers are oil fired and the installation presents many features of interest. Perhaps the most noticeable feature to the casual visitor is the extreme cleanliness of the plant in general. The floor throughout is of red tile and the entire absence of ashes and other dirt always present when coal is used makes it easily possible to keep the boiler room, and the apparatus installed in it, spick and span.

Four Simplex oil burners, two to each boiler, are installed. These burners are made by the Standard Oil Burner Co. of Oakland, Cal. Each burner is fitted with a one-half horsepower direct current motor, which serves to drive the blower for air supply and gear type oil pump, both mounted on the motor shaft. The oil pump pumps direct from the oil tank and the surplus over that which is allowed to flow through the regulating valve, flows back through a return header to the oil tank.

The whole mechanism is mounted on a swinging plate

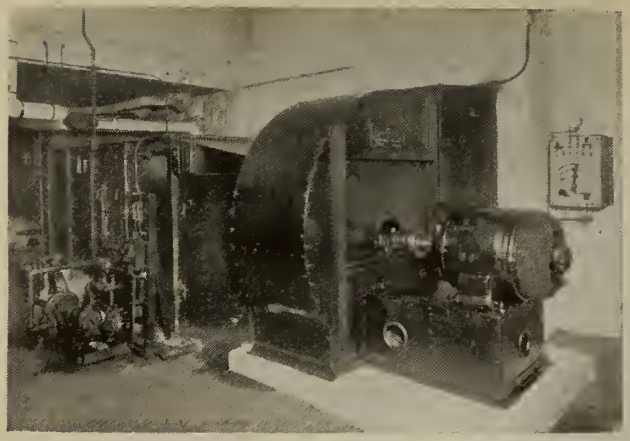

FIG. 1—CARRIER AIR CONDITIONING APPARATUS.

hinged to the boiler front so that when the burner is cut off it can be swung away and the illiptial hole, shown in Fig. 3, closed with a plate. This prevents injury to the burner from the incandescent brickwork of the connection chamber. Each motor is fitted with a starting rheostat and knife switch, this equipment being mounted on a marble panel adjacent to the boiler front.

Electrical connection is made to the motor by flexible conduit and the oil connections are made through a special union which permits the burner to swing easily through the necessary angle. Fig.3 shows the front elevation of boilers and the different positions in which the burners are shown enable their details to be made clearly visible.

The oil tank supplying fuel oil to the burners is placed three feet below the basement floor and is capable of holding 2,015 Imperial gallons of oil. It is 15 ft. long by 5 ft. diameter and is provided with dished heads.

A small coal fired heater and a hot water tank are provided for the furnishing of hot water to wash basins, shower baths, etc.

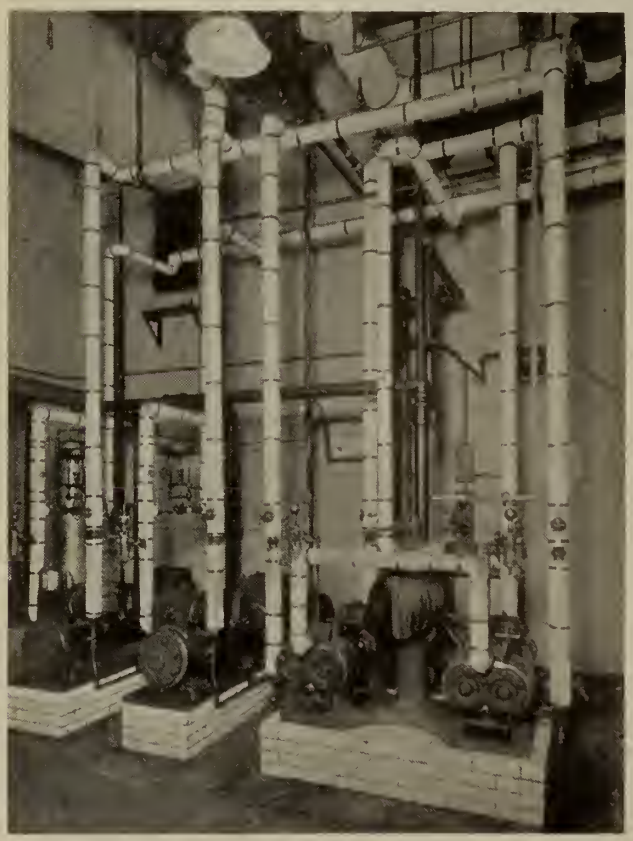

FIG. 2—BOILER FEED AND VACUUM PUMPS, NO. 1 DUNHAM VACUUM HEATING SYSTEM.

The drinking water is all filtered and cooled. Two sets of Loomis-Manning Filters, installed by the Loomis-Manning Distribution Co., Philadelphia, are used. These serve to render the water sparkling, clear and free from any contaminating influence. From the filters the water passes to a cooler operated by a small York vertical two cylinder ammonia compressor. This compressor is driven by a Westinghouse 5 h.p. d.c. motor. A Worthington single stage centrifugal pump driven by a one h.p. motor circulates the drinking water through the system. By keeping the water in constant circulation, it is always at the proper temperature at the faucets and no water need be run off to waste on account of its being too warm. The drinking water faucets are entirely separate from wash basin faucets, and the piping has no connection with the lavatory supply.

In connection with the wash basins throughout the building, it is interesting to note that they are fitted with special faucets made by The H. Mueller Mfg. Co., Ltd., Sarnia.

FIG. 3—BOILERS SHOWING OIL BURNERS. THE ONE ON THE LEFT IS IN RUNNING POSITION, THE TWO MIDDLE ONES SHUT DOWN AND SWUNG OUT, AND THE RIGHT-HAND ONE SWUNG CLEAR AROUND TO EXPOSE FIRE HOLE.

These work on the self-closing delayed principle so that they can be adjusted to remain open for any length of time desired. By this means the basins can be filled to any depth desired without danger of flooding and without the necessity of keeping the faucet open by hand as is the case with all other self-closing faucets.

Two fire pumps are installed, each of the two stage type made by Worthington, and each driven by a Sprague 7½ h.p. d.c. 230 v. motor. These pumps serve to fill two tanks on the roof of the building and are arranged for automatic or manual operation. The starting mechanism is unusually complete and the switchboard of Cutler Hammer make, in addition to the control apparatus for the motors, is fitted with tank indicators and bell alarm.

A low voltage storage battery system is installed and furnishes control for the automatic feature of the fire pump installation, high and low water alarm, elevator signal lights and other features of a similar nature.

Two duplicate 18 volt batteries are installed and a one h.p. Sprague motor-generator set is used for charging. The battery switchboard carries battery charging switches, generator circuit breaker ammeters, voltmeters and the usual feeder circuit knife switches.

A marble distribution board also forms part of the electrical equipment. Energy for power and lighting is obtained from the central station through a 110/220 volt d.c. service. This board presents a very neat appearance through having all the fuses mounted on the back and only the knife switches showing.

Mr. Maxwell Mongraw is Chief Engineer, and Geo. Bains, Plant Superintendent.

The installation of this power plant was done by W. J. McGuire, Toronto.

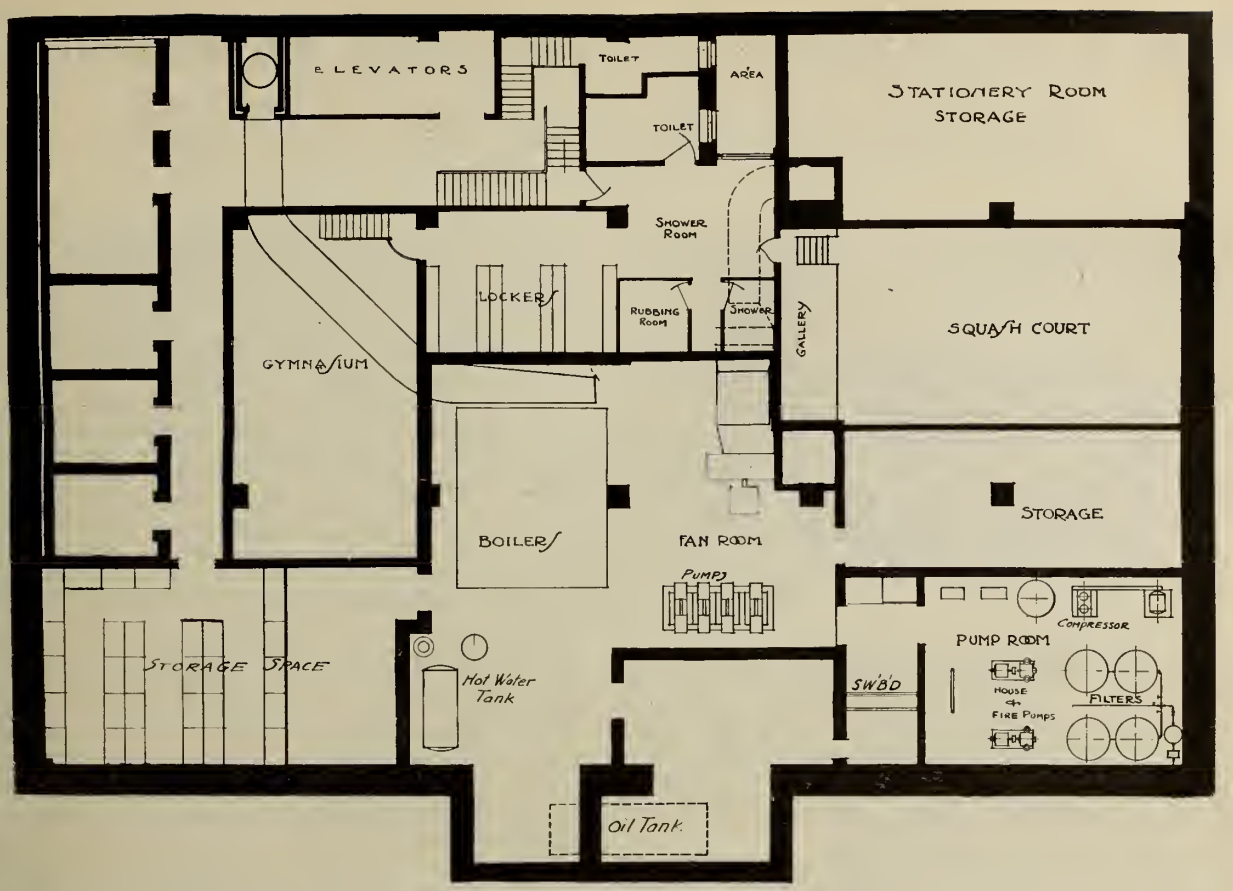

FIG. 4—BASEMENT PLAN SHOWING POWER PLANT EQUIPMENT AND OTHER FEATURES.

A Revolution in Wireless Telegraphy

The more closely the subject is studied the more apparent it is that the three-electrode thermionic vacuum tube has wrought a revolution in wireless telegraph methods. Until the year 1914 all the most powerful transmitting stations in the world generated waves by sparks, and signals were received at nearly all stations by means of crystal or magnetic reflectors. The spark methods of generating waves involved the use of very large antennæ for spanning great distances, and at receiving stations which wished to listen to stations more than even a hundred miles away very large aerial structures were necessary. To-day, most of the high power stations are continuous wave stations, while at the receiving end new modes of detecting these continuous waves have been introduced. This is where the three-electrode tube enters the arena, and has almost removed the necessity for any antennæ at all at receiving stations. For example, under reasonable weather conditions, it is quite easy to listen to the messages coming from stations on the other side of the Atlantic by using a receiving circuit of which the receptive element is a small coil of wire 3 or 4 feet square. Thus, so far as receiving goes, it is impossible to intercept practically all the great stations on one-half of the globe by means of apparatus contained wholly in one room, or even in a cupboard. This does not mean that the use of an antennæ for reception is abolished; on the contrary, when these highly magnifying methods are put into operation with large antennæ for the purposes of reception, the range over which signals can be received is extended very far beyond what it was in 1913, and in consequence it is possible under reasonably good weather conditions to receive at the antipodes the signals from a modern high-power station. In accomplishing this the magnifications in use amount to several hundred thousand-fold. All this is the work of a thing which looks like an ordinary electric light bulb with a few extra pieces of metal in it—the three-electrode tube.

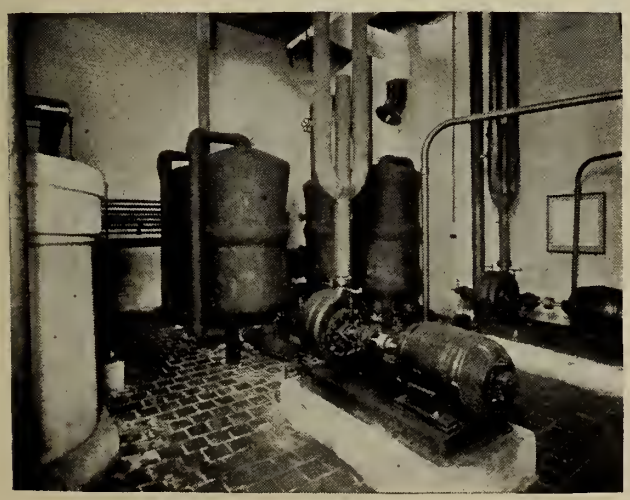

FIG. 5—SHOWING FIRE PUMPS AND FILTERS FOR COOLING WATER.

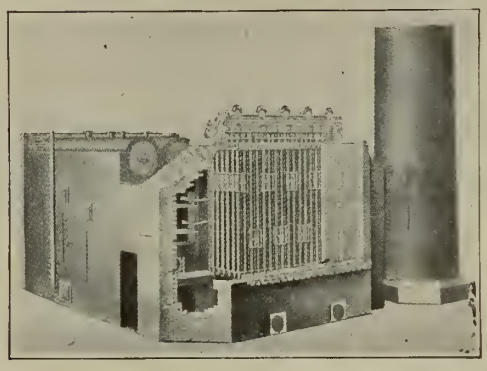
This is not all the story, for when the tube is made in large sizes it can be used for producing alternating current of high frequency and of considerable power, and then it can be employed for transmitting electric waves. Moreover, by giving another aspect to its functions, the triode can be used for modulating the alternating current just spoken of, and so for impressing upon the waves the human voice. In this way speech has been transmitted freely across the Atlantic, being received, it need hardly be said, at the distant end by the aid of other of the protean properties of the ubiquitous three-electrode tube. In passing, it is worth remarking that the process of thermionic evaporation briefly mentioned above is really, in the opinion of Dr. Eccles, a method of obtaining electricity from matter without the use of moving parts—that is, without machinery.

The Economizer in Power Plant Operation--I.

The Following Article Reprinted From a Paper Read Before the Boston Section of the A.S.M.E. Gives Some Valuable Data on Economizer Operation



EVERYWHERE abroad—in England and throughout the leading countries of the Continent, the economizer is considered a necessary accepted part of the equipment of every steam plant, and its use is steadily growing throughout the world. In Germany, commercial coal averages between $4 and $4.50; but in England, the home of economizer origin, coal sells at 75c to $3.00 per ton, depending upon nearness of mines.

Here, as in the United States, coal comparatively costs about the same, yet several engineers and owners consider the economizer utility doubtful, and even some prominent men consider it to be altogether dispensable. The reasons that are advanced more than any others by these opponents are commonly:

First. Complication and expense for providing space.

Second. The draft is so seriously affected that extraordinarily high and costly chimneys must be installed to offset the economizer effect, or else powerful artificial draft apparatus must be installed.

Third. The feed water can be as highly heated as desired more simply and at less outlay by means of waste from auxiliaries.

There can be added other objections, but they would appear to be only important to some individual proposer, the more common reasons have been chosen.

Simplicity cannot be denied as a desideratum, but no one here would choose the simple life of Diogenes in his tub, although admitting the difficulty of determining the elimination of many things from his home. Therefore, above simplicity we prefer the possession and care for articles that appeal for their beauty, for comfort, for labor-saving, for economy, etc. Civilization is complex. Economy that does not sacrifice reliability is a higher attainment towards the ultimate of human efficiency than an attainment of merely stern simplicity.

Complication and Expense for Providing Space

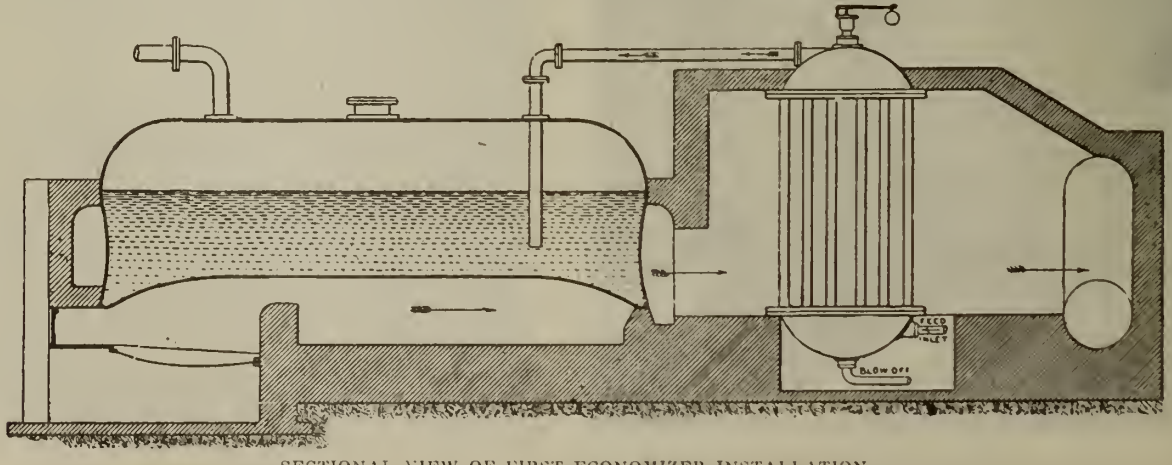
The economizer is not signally different to any other adjunct found in the power plant. Any apparatus or even recording device has its in and outgoing attachment connecting it with the plant. Economizer connections once made seldom need any further concern for adjustment or handling. The feed water supply is regulated in the same manner and the draft likewise day in and day out precisely as if the plant had no economizer. The piping and flue connections are not troublesome to the engineer capable of designing intricate power station equipment.

Perhaps the complication in mind is the occupation space and building features. The answer to this is, that a consulting engineer or architect is engaged upon the supposition that he is able to design a plant or building that will satisfactorily incorporate and house the necessary and desirable features needed to uses of the owners.

With reasonable study, it is seldom that the cost of the boiler building cannot be kept to the same expense with economizers as without them. Space above the floor can in some way be engineered and the room below the economizer well utilized. Instead of a higher boiler building, inexpensive skylight scuttles or skylight monitors, which also give added daylight and ventilation, can be built above the machine for tube removal. Even special outside buildings can be designed to usefully utilize the space underneath the economizer for fire pumps, lockers and baths for firemen, or for store parts, an often unthought of provision.

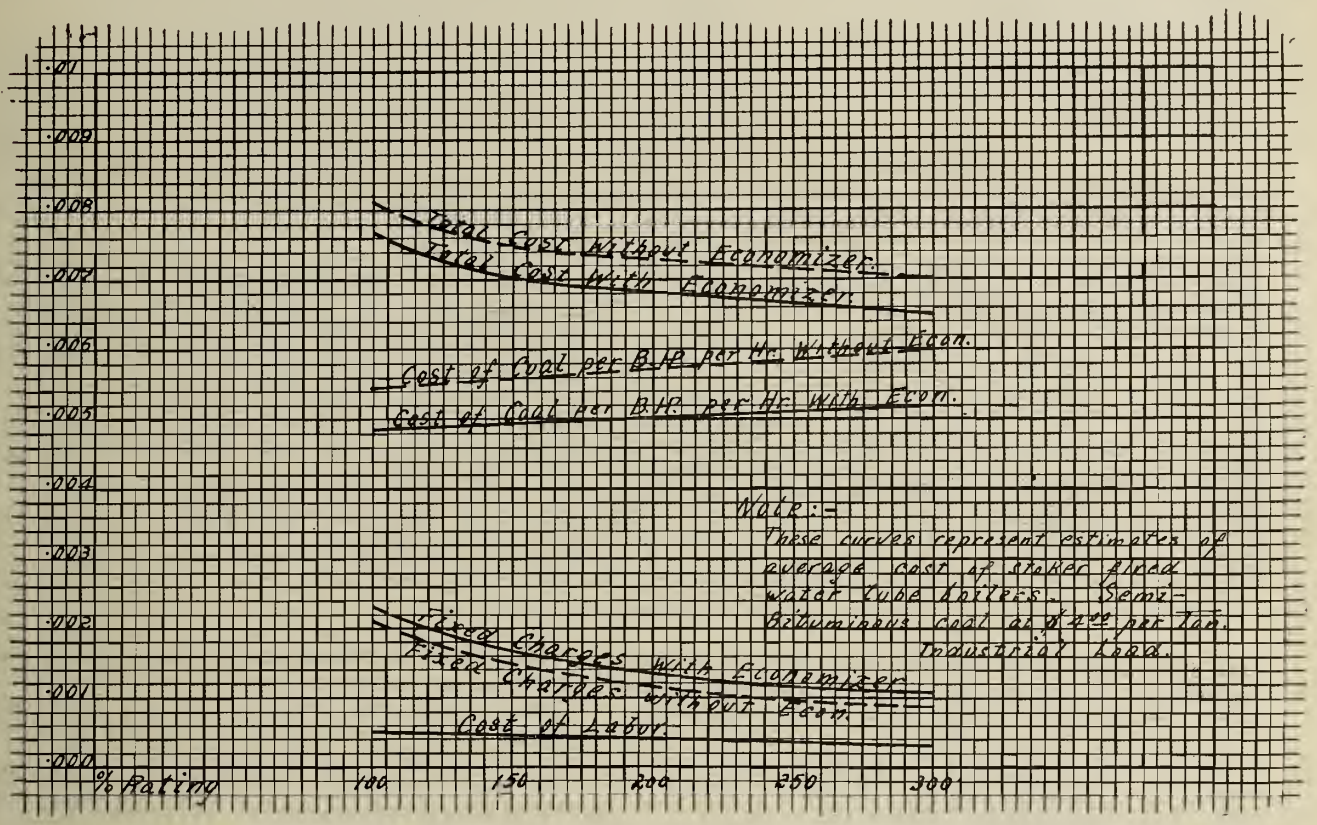
What a person believes in with all his heart and wishes to accomplish he will usually succeed in doing, even though physical or financial restrictions prescribe certain limits, while without that spirit the slightest encounter of difficulty appears insurmountable. Many economizers have been put into stations where the original consulting engineer had no use for them and seemingly thought there was no possible space to employ them.

When some economizers do not work well under ordinary conditions of draft or to over-load, or with stokers, the man with the ideals and perception will not accept those results with content, but inquires the wherefore that these tests and results fell short of a better attainment found elsewhere.



SECTIONAL VIEW OF FIRST ECONOMIZER INSTALLATION.

Referring to the chart herewith: "Cost of Steam to Boiler Rating." This is an interesting study showing if an economizer was introduced it would lower the cost of coal line about 10 per cent., and probably better, keeping this line more even and reducing the ascending coal cost shown.



CURVES SHOW FIXED CHARGES, TOTAL COSTS AND COST OF COAL WITH AND WITHOUT ECONOMIZERS.

It has been assumed that equipment is figured for boilers, stokers, building, chimney, etc., without economizer at $47 per B H.P. If we add 11 per cent. for economizer installation, or $5 per B.H.P., it would raise the fixed charge line accordingly, and, as the total cost line is obtained by the addition of the 3 curves below, it has a marked lower position by effect of the lowered cost of coal. This new line looks handsome and worth trying to obtain.

Examples of insufficient draft are as frequently found in the average old plant without economizers as with them. Examples of going plants operating economizers successfully, with ordinary chimney heights, are to be readily found everywhere under all varieties of conditions—all types of boilers—all types of grates and stokers —all kinds of coal, etc. All of which should teach that finding an economizer plant at fault in the matter of draft, the instant conclusion that the apparatus is the cause of the trouble, would be a rash judgment. It may be true in some rare instance that cutting out the economizer has improved the draft, due, not to the effect of the apparatus, but to poor engineering design of angles and openings into the economizer. This has been proved when these conditions are altered, by the economizer going back into use with better results than ever. When a plant has grown so that the gas volume really overcrowds in the economizer chamber, then a remedy is easily had by allowing the gases from one or two boilers nearest the stack to go direct without passing through the economizer at all, thus reducing the volume to be handled through it to the proper limit of its ability. Simple as this sounds, it is seldom thought of, as the growth has been gradual for years with satisfactory results for most of the period until the owner discovered the economizer restriction, when his cure has been to arbitrarily cut it out altogether, or until this remedy or some other even more simple change is suggested to effect the desired improvement. It is a matter of surprise how often the draft difficulty has been found to lay elsewhere than in an economizer.

In 1891, Mr. Geo. H. Barrus had noted this very point in his book, "Boiler Tests," that it took actually more draft to operate the plant without an economizer than with it, and comments on this as follows:

"It is important to note the effect which the use of the heater has upon draught. The amount of draught suction which existed in some of the above examples and in one additional example, together with information regarding quantity of coal burned and other matters bearing on the question, are given in the accompanying table.

"The effect of a reduced temperature of the escaping gases, which always accompanies the employment of the heater, is seen in every one of these instances to reduce the draft power of the chimney. In Boiler No. 59 the temperature is reduced from 645 degrees to 365 degrees and the draught from 41/000 of an inch to 32/100 of an inch, or 22 per cent. This is with an eighty-foot chimney. In the last case a reduction of temperature from 575 degrees to 373 degrees is accompanied by a reduction of draught from 97/100 of an inch to 69/100 of an inch, or 29 per cent. This is with a 140-foot chimney. Although the general effect of the flue heater in this respect is unfavorable, a large amount of draught is required to operate the boiler, in every instance where the average draught is given, when the heater is thrown out of use. This is not due to any peculiar action of the heater, but evidently to the increased quantity of coal which must be burned in order to make up for its absence."

The fuel bed resistance would be less to produce a given boiler output, because there is less coal used and hence the less resistance as noted by Mr. Barrus. This is just as true with stokers as without them. It is just as true for overload conditions as for normal. To develop overload conditions, it does take enormous draft pressures to get the needed air through the thick fuel bed. Provide therefore such proper pressure if you will,

SCHEDULE OF TEST.

and, indeed, must do so, and then add a properly designed economizer. The top blanket layers of fuel are then taken off by the economizer and the draft is eased wonderfully. So if, therefore, adequate draft has been provided, either natural or artificial, suitable for operation without economizers, then there will be no difficulty in keeping up steam with a less expense for coal.

"The speaker first described with the aid of illustrations the dependence of chimney costs upon their height and inside diameter, the relations between the chimney heights, the hourly consumption of fuel and the operating costs and temperature of the gases entering the chimney.

"Of great importance in determining the gross dimensions of the economizer, are the temperature of the entering water and the drop in temperature of the flue gases that are employed.

"The entire installation will be cheapest when the utilization of the flue gases in the economizer goes the farthest. How far the flue gas temperature is then econ-

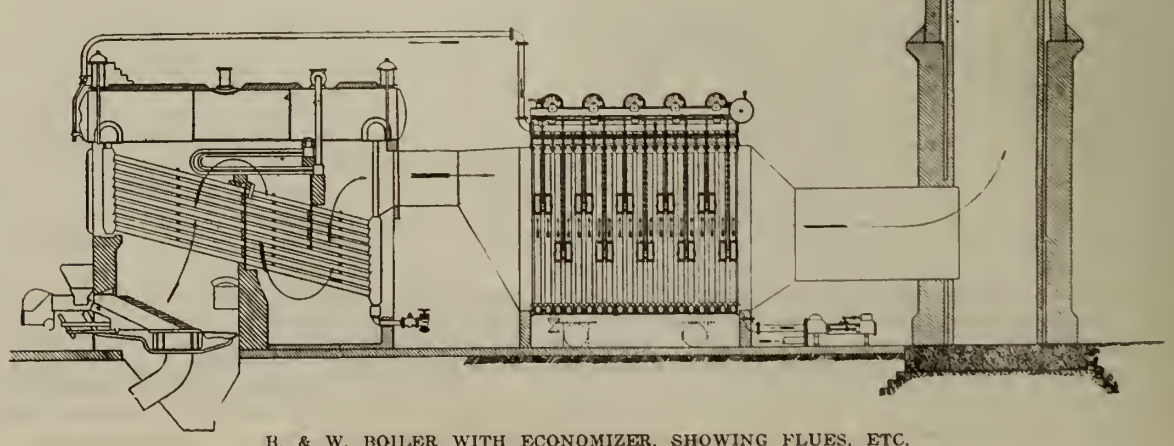
The following abstract of a report by Engineer Gleichman, presented at the Munich convention of the International Association of Steam Boiler Inspection Societies, and translated from "Gluckauf," is of interest to those having to do with economizers:



B. & W. BOILER WITH ECONOMIZER, SHOWING FLUES, ETC.

omically utilized depends upon the temperature of the feed water. If the service is variable it is proper to proportion the outfit for the average efficiency.

"The question whether, in large plants, one common economizer or separate equipments behind each boiler should be used cannot be settled by general principles since it depends upon working conditions. With very regular load a common economizer would be advantageous because of its cheaper first cost and smaller amount of outside radiating surface to the single chamber, while, where boilers are frequently cut off, as in electrical stations, individual economizers are preferable, there being danger that otherwise a too great cooling down of the flue gases may reduce the draft.

"Summing up, the question of employing economizers may be answered by saying that they are primarily of use in enabling the designer to lay down an economical plant, by most completely utilizing the flue gases and obtaining the best combustion. Their field of usefulness will widen the more that small boiler plants disappear and hand-stoking gives place to mechanical. The size of an economizer as compared with the boiler heating surface—which cannot be settled by a fixed ratio, since it depends upon the feed water temperature—should increase with the pressure and with increased attempt to employ in the boiler only heating surfaces of high value."

Note the attitude of Mr. Gleichmann upon the matter of draft. He treats it as a reasonable affair to be designed and laid out to requirements. Just as any practical man would give thought to provide the right air spacings of grates, determine the use of large or small tube areas and forethought to other resistances, to the draft for properly operating a boiler to suit conditions. No fear or special anxiety is given to such matters, although it is important that they should be taken into account.

An interesting test at the Clark thread mill, where boilers were intentionally put in, designed to run at over-rating, using an economizer with induced draft, producing a boiler horse power with less than half the usual rating of 10 sq. ft., is worthy of record.

The test was made under Mr. Abercrombie, the expert of the thread interests in Scotland and America, and shows definitely a less draft needed for over-rating conditions than other practicing engineers would require without economizers.

"Induced Draft," occasionally we find, is still regarded as "some bogey." The subject of Induced Draft is a broad one, but in general, I would say that these operate more satisfactorily than forced draft alone, which later produces arduous conditions to the maintenance of the stokers, furnace, boilers and a strain upon the labor. The forced draft stokers need to be watched for holes in the fire, which have to be hand-treated under extreme difficulty, with steam falling away until they are remedied. This is a frequent experience. Some forced draft stoker customers have considered it advisable to add to their retort capacity to cut down the blast effect, although they were developing nowhere near 200 per cent. of running. These owners had installed the size of their equipments as recommended by the stoker concern. Forced draft to hand-fired boilers after a five years' use produces a sad looking plant; while induced draft keeps operating indefinitely for years in smooth steady fashion.

This line of argument is not fair to either type of draft. Conditions must be maintained aright for any apparatus to keep performing its duty—the induced draft has a wider range of accomplishment to changed conditions and makes for more agreeable plant operation. This is due largely to its greater size to handle the same air weight as would be forced through the fire by the blast fan type.

In the great paper mills of S. D. Warren & Co., and Hollingsworth & Whitney, the induced draft is found dependable 144 hours every week, and in many public service stations they are found reliable for service every hour of the entire year.

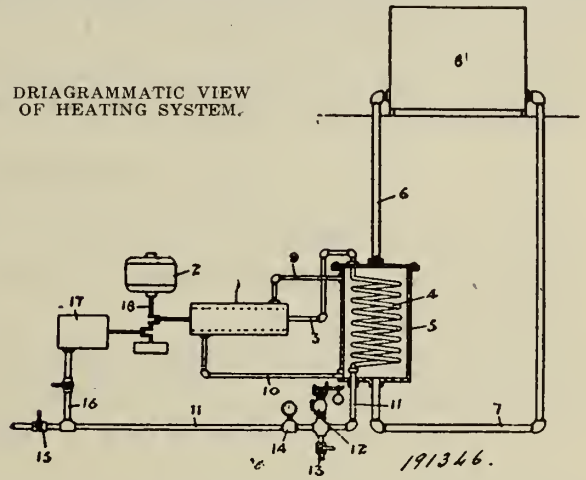
(To be concluded)

A New Heating System

A NEW heating system of considerable interest forms the basis of a recent patent issued to Robert Cairns, Chief Engineer of the Farmers Dairy, Toronto. The accompanying illustration shows in diagrammatic form the principle of the system as outlined in the patent specifications.

The principal feature of the invention consists in the novel method of heating a circulating medium by the compression of air by electrical means and the passing of the compressed air through suitable radiating coils to convey the temperature to the water of the circulating heating system, and to utilize the reduced temperature compression for other purposes, or to expand the air to relieve the consumption of electrical energy in initial compression.

The air compressor (1), which can be of any suitable type, is operated by an electric motor (2). The compressed air is carried from the outlet of the compressor by a pipe (3) to a radiating coil (4). This coil is enclosed within a tank (5), which is connected to a suitable water heating system of the circulating class by the pipes (6) and (7). The heat of the compressed air passing through the coil heats the water in the tank, which rises through to pipe 6 to the radiators and returns by pipe 7. The heat of this compressor is further utilized by the connection of the water jacket of the compressor to the tank (5) by means of the circulating pipes shown. A pipe (11) leading from



the coil (4) is provided with an adjustable safety valve (12), which may be regulated to relieve at different pressures, and below the safety valve a drain cock is provided which will allow condensation to be drawn off.

A suitable pressure gauge is arranged in the lengths of the pipe and cut-off cock cuts off the pipe (11) from an extension which may be connected to any suitable apparatus which it is desired to operate by compressed air.

A branch pipe (16) leads from the pipe (11) to a re-expanding cylinder (17), which is connected with the shaft (18) of the electric motor so that the pressure of the cooled compressed air remaining may be utilized to relieve to a certain extent the work of the motor. The safety valve is of the adjustable type so that it may be adjusted to relieve at various pressures. The adjustment may be regulated to increase or decrease the temperature of the circulating water through the heating system, for as the pressure increases the temperature rises.

It is stated that a system such as described has in experimental tests shown extremely satisfactory results, and when it is considered that the compression of air to 100 lbs. produces a temperature of approximately 450° Fah. with an intake temperature of 60° Fah., the heating of water can be accomplished to suit the requirements of very extreme weather, besides providing cold air for refrigerating or cooling purposes, and the inventor further states that the application of electric energy to the production of heat in the manner described is entirely novel, and it is further stated that many variations in the actual apparatus may be made without departing from the principles of the invention.

Application Forms for Graded Certificates

The Forms Given Below Are Those Which Will be Issued Shortly by the Board of Stationary Engineers for Both Engineers and Plants—Certificates Will be Graded on These

IN our Oct. 6 issue the regulations respecting the grading of stationary engineers were printed. Below we are giving the application forms which will be sent out in connection with this grading of both engineers and plants. It will be seen that two different forms are shown. The engineer himself has only to do with the first one, as it concerns him alone, while the other one has to do with the plant. The form which the engineer is required to fill out will be sent out shortly by the Board of Stationary Engineers to all those holding certificates at present. When filled out and returned by the engineer, the information given will serve to determine his status for the coming year, and whether a second or third-class certificate will be granted him.

For this reason it is earnestly requested by these who will have charge of the grading that all information asked for be given fully and as accurately as possible. This, it will be readily seen, is to the engineer's own advantage.

One thing more, the fee for renewal for the year 1920 will be only one dollar, and not the amount required under the regulations for an entirely new certificate.

A number of inquiries have already reached POWER HOUSE as to what steps an engineer should take for the obtaining of the new certificate. The answer is easy: do nothing but wait for the application blank to come to you, fill it in and return it. If by any chance you are overlooked, some time in the latter part of the year write the Board requesting one.

Engineers having no certificates at present and passing the present examinations up to the last day in December will be given one of the present certificates, and this will be exchanged at the proper time for the 1920 certificate, either second or third, corresponding to qualifications.

The second form will be filled out by the owner of the plant, or likely by the engineer for the owner. This form will be sent to the owner of the company direct at a later date than the engineer's application form. It asks for sufficient information for the plants to be graded properly.

Application For Renewal of Stationary Engineer's Certificate, 1920

I, ...
(Name in full, no initials)

of .....hereby make application for a graded certificate for the year
(Place)

1920, same to be granted to me in lieu of renewal of my present non-grade Stationary Engineer's Certificate. The sum of One Dollar is enclosed herewith.

AND I hereby affirm that I am a British subject, the holder of Stationary Engineer's Certificate No. ..... last issued to me in the year....., and that I have had experience with boilers and engines as follows:

State length of practical experience, giving dates to cover each period of your employment at separate plants:

....

....

State in what capacity you were employed:

.....

.....

State if you hold certificates from any other Boards; if so, submit same with this application for verification:

....

Give names of your previous employers:

....

Give name and address of your present employer:

....

Give length of time in his employ:

....

Give B.H.P. (Boiler horse power) capacity of plant or plants you have handled:

....

Give B.H.P. of plant where you are now employed .....: also steam pressure carried.....

State kind of boiler or boilers now under your care, whether return tubular, water tube, horizontal, locomotive, marine, etc. ....

.....

....

Give dimensions of boiler or boilers.....; length and diameter of same.....; number of tubes.....; diameter of same.....; area of grate surface.....

N.B.—No details of an applicant's experience should be omitted, as this information will be used in deciding the grade of certificate he will be granted.

I hereby make oath and say that the statements herein contained are to the best of my knowledge and belief true in substance and in fact.

Sworn before me at the.....
of..... in the.....
of .....this.....day of
.....19..
.....
A Commissioner, etc.

.....
Signature of Deponent.

NOTICE.—All questions on the application must be answered in detail, otherwise a Third-class Certificate only will be issued from same; pen and ink to be used.

Certificate No.....

Signature of applicant.....
(Write plainly)

Address .....

Signature of Deponent.

KEEP TANK VENTS OPEN

THE attention of works engineers to the necessity of close inspection to see that tank vents are open and unclogged is emphasized by a writer in "Factory."

Every large oil tank has a vent. Tanks which hold other supplies besides oil must also be vented in a positive manner to prevent gases being confined. There is another function which the vent performs that is fully as important.

When a tank of liquid is being pumped down, the top will soon collapse if the vent pipe becomes closed. Such an accident is of frequent occurrence and the difficulty of bringing the tank crown back into its normal position is great.

The usual type of vent in an oil tank is a gooseneck of sufficient cross section. The gooseneck projects through the upper part of the tank and by means of a return vent terminates in an open-ended drop. On the open end is usually placed a fine copper or brass-mesh screen. The opening in this way has a chance to become stopped up by dirt sticking to this screen and forming a hard layer.

BELT SPEED AND LENGTH RULE

TO find the speed and length of belts "Belting" gives the following:

"To find the speed multiply the circumference of the driving pulley in feet by the revolution per minute. For example, a pulley 12 in. in diameter makes 150 r.p.m. What is the speed of a belt traveling over this pulley? The circumference in feet is equal to 3.1416 by 150, the number of revolutions per minute equals 471.24 ft. per minute, or nearly 471¼ ft. To find the circumference of the pulley, multiply the diameter by 3 1/7, which product multiplied by the revolutions per minute gives the speed of the belt per minute. To determine the length of the belt, add the diameters of the two pulleys, divide the result by 2 and multiply the quotient by 3 1/7. Add the product to twice the distance between the centres of the shafts and you have the length substantially."

Fuel Economy is Still Desirable

FORGETFULNESS is a common failing and unless repeated to-day we are apt to forget the lesson of yesterday. During the period of war activity much was heard about the necessity for fuel economy. Governments, engineering organizations, and the press, technical and lay, laid stress on this feature of industrial conservation. This was as it should be, for the lessening of fuel consumption not only relieved the labor shortage but rendered available coal for essential industries.

While the war has been won, fuel conservation is still well worth considering as a factor in the winning for ourselves the fruits of the peace through which we have been struggling to a better civilization.

Many hare-brained theories are being advanced by half-baked economists and radicals of a less disinterested type for the remaking of the world, and for its betterment as a place to make a living in, but none of them has as much to commend it as the old-fashioned idea of hard work, greater production individually and in the mass.

Greater production is only one aspect of efficiency and includes not only increased production of material things but their wiser utilization. The personal inspection of possible sources of power waste, whether in the engine room, boiler room, or factory, will do much to lessen needless waste of coal, and this together with the proper training of operatives and investment of apparatus tending to economy will do much towards lessening the use of all Canada's fuel resources and the importation of coal from our neighbor to the south. Money in pocket will also result from this practice whether the power plant owner takes the more altruistic view or not.

Boiler room losses are easy to detect and are easily remedied. Air infiltration, leaky baffles and excessive heat radiation are only three of the possible sources, to mention nothing of improper methods of firing. Losses from bare steam pipes through condensation are rarely estimated at their true value and covering, which saves 70 to 90 per cent. of the radiation loss, is, in all cases, good investment. Insulation should cover not merely the pipe itself but also its flanges, fittings and the surface of any accessories with which live steam comes into contact.

A steam leak is small in itself but great in its appetite for coal. Three dollars a month is too much to pay for a one-sixteenth-inch hole in a steam line. It is better to have the leaky gasket, fitting or other cause replaced or repaired. Leakage of steam at stuffing boxes is too often prevented by an unwise tightening of the gland nuts. This is going to the other extreme and requiring more steam for work which doesn't appear at shaft. A pump may require as much as 30 per cent. more steam from this cause alone.

Steam traps are another potential source of loss through steam leakage and the best of traps is none too good. And these sources of loss are only a few of the many possible. On the other side of the ledger are the many power plant accessories made for the express purpose of securing economy in operation. The majority of these find their place in the boiler room and if wisely used fulfil expectations. Recording and indicating apparatus go hand in hand with means for securing better combustion with less labor.

Eventually, in every country, the burning of fuel will be an exact science carefully worked out even in the smaller plant and probably subject to some form of control. The coal resources of the world are not inexhaustible and their wise utilization is a matter of concern to everybody.

Man is optimistic by nature and readily makes himself believe that other sources of power will be found, possibly twelve-mile deep shafts into the earth's crust or interatomic energy will be available, but carbonaceous fuels are not replaceable in some industries.

Did You Ever Do This?

I MET my friend upon the street, his face was out of plumb; his countenance was far from bright, in fact 'twas sour and glum—he looked as though his wife had just begun to try on him, some sixteen kinds of fancy eats to stow beneath his skin.

He waddled 'cross the street, he did, with stride both poor and lame; you couldn't call it rheumatiz, nor was this fellow lame.

But I had known this chap for years, in seasons good and bad, nor had I seen his map before so wrinkled nor so sad. I thought some grief had come to him and smote him on the jaw, or else he'd been pulled into court for bustin' up the law.

So I drew nigh unto this prune, and sought to cheer this boy. I cracked ten jokes and cackled, too, to spray his soul with joy.

He never budged an inch, by heck, his sufferin' was intense; there camped upon his carcass now a spasm most immense.

"Come tell me now what's all about, this grief what's smote your life—be it an illness in the house, or have you canned your wife?"

He drew my head toward his chest, and bade me flop an ear, and meantime tried to choke a sob and boot away a tear—and then he lifted up his voice and told me of his woes—he had that day put on his hide his woollen underclothes!—ARK.

Appointment Made to Board of Examiners

In connection with the grading of certificates in Ontario, an appointment has been made to the Board of Examiners whose duty it will be to carry out the provisions of the Act. Chas. Mosely has assumed the duties of assistant to the chairman of the Board, Mr. W. C. McGhie. Mr. Mosely's duties will be those of a permanent examiner and will entail his travelling from centre to centre throughout the Province. Mr. Mosely was formerly in charge of the Power Plant at Toronto University, the supervision of which will be now under his son, Chas. S. Mosely, Junior.

An experience of forty-five years as operating engineer, 30 years of which were spent in charge of power plant operation will bear evidence to Mr. Mosely's capabilities in filling his new position.

A New Water Turbine

The need for bridging the gap between the higher speed of the Pelton wheel and lower speed of the Francis turbine has been recognized, and it is now reported that a Budapest engineer has succeeded in providing this intermediary machine. It is stated that the new turbine can be installed as simply as a water wheel, but presents the advantages as compared with water wheel working of higher efficiency, lower first cost, and reduced operating and repair cost. Essentially the wheel consists of two discs carrying a series of cylindrical blades, and tests with model wheels have indicated efficiencies of 87 to 89 per cent.

Readers—Notice!

ON January 1st the subscription price of POWER HOUSE will be two dollars per year. Last spring, in reply to a questionnaire we sent out to all subscribers, it appeared to be the universal opinion that for a semi-monthly journal like POWER HOUSE, two dollars per year would be a minimum subscription price. Now, we're here to help the engineer—we're doing so, constantly. We should get three dollars per year at least. But two dollars 'twill be—after January first next.

In the meantime subscriptions will be accepted (also renewals) at one dollar per year. Send in yours to-day.

Germany's Copper Shortage

ONE result of the Allied blockade of Germany was seen in the many expedients to which the Hun was forced in the obtaining of the 120,000 tons of copper necessary annually for military requirements. Home production was only about 23,000 tons per annum in pre-war days and this was reduced to about half owing to the mobilization of the miners.

The *Technical Review* in a translation of an article from *Technick und Wirtschaft* gives some further interesting data relative to the economies practised. During the first two years of the war the deficit was partially covered by booty from Belgium, France and Russia. Large quantities of scrap copper and brass were collected from munitions works and from fittings on naval and mercantile vessels, the scrap being smelted and refined.

Bronze scrap with about 90 per cent. copper and 10 per cent. zinc was successfully treated by electrolysis, the metal being formed into cathodes which were electrolyzed in copper sulphate, several weeks being required for the deposition of the copper. The dried sludge from the process contained up to about 60 per cent. of tin which was recovered as pure metal.

To minimize the consumption for army purposes all brass and copper uniform badges were abolished and zinc replaced brass in munitions. In spite of rigid economy the consumption remained enormous, and by the end of 1916 stocks had become exhausted. This necessitated the substitution of iron in cartridge cases, caps and driving bands, all tubes and wires in electrical plant, torpedo tubes and propellers on small war vessels. For medium shells, zinc driving bands were used, and electrolytic iron for those of large calibre.

In the navy, cast brass (55-60 per cent.) replaced Admiralty bronze, the tendency of the former alloy to pipe and froth in casting hollow articles being counteracted by making the gate of equal capacity with the mould, and allowing time for the included oxides to rise to the surface before actually running the metal into the mould. The risers were also plugged and the imprisoned air only released when the mould was nearly full. These alloys failed to withstand friction and, therefore, parts exposed to heavy wear had still to be made of Admiralty bronze.

Thomas in Detroit "News."

Why did they civilize us when we were happy?

Laying Out Boiler and Engine Foundations

Every Stationary Engineer Should be Able to Lay Out and Superintend Excavation Work, Mixing and Pouring of Concrete Foundations and the Erection of the Machinery on Them

By T. H. FENNER, Associate Editor

THOUGH many stationary engineers are never called upon to carry out installation work, everyone should know the methods to be employed in laying out foundations, supervising the building of concrete forms, and the proper mixture of concrete to be used in making the foundation. He should know something of the different kinds of earth and their bearing qualities, and the necessary safeguards to be employed where the land is of an unstable nature.

After the foundation is completed he should know how to proceed with the erection in the quickest and safest possible way. When it is necessary to employ an erecting engineer from the machinery contractor, the very cheapest he can be obtained will be around $10 per day exclusive of travelling and hotel expenses. The engineer in charge of the plant can thus save his employer a large amount of money if he can carry on this work, and incidentally show he is something more than an engine driver.

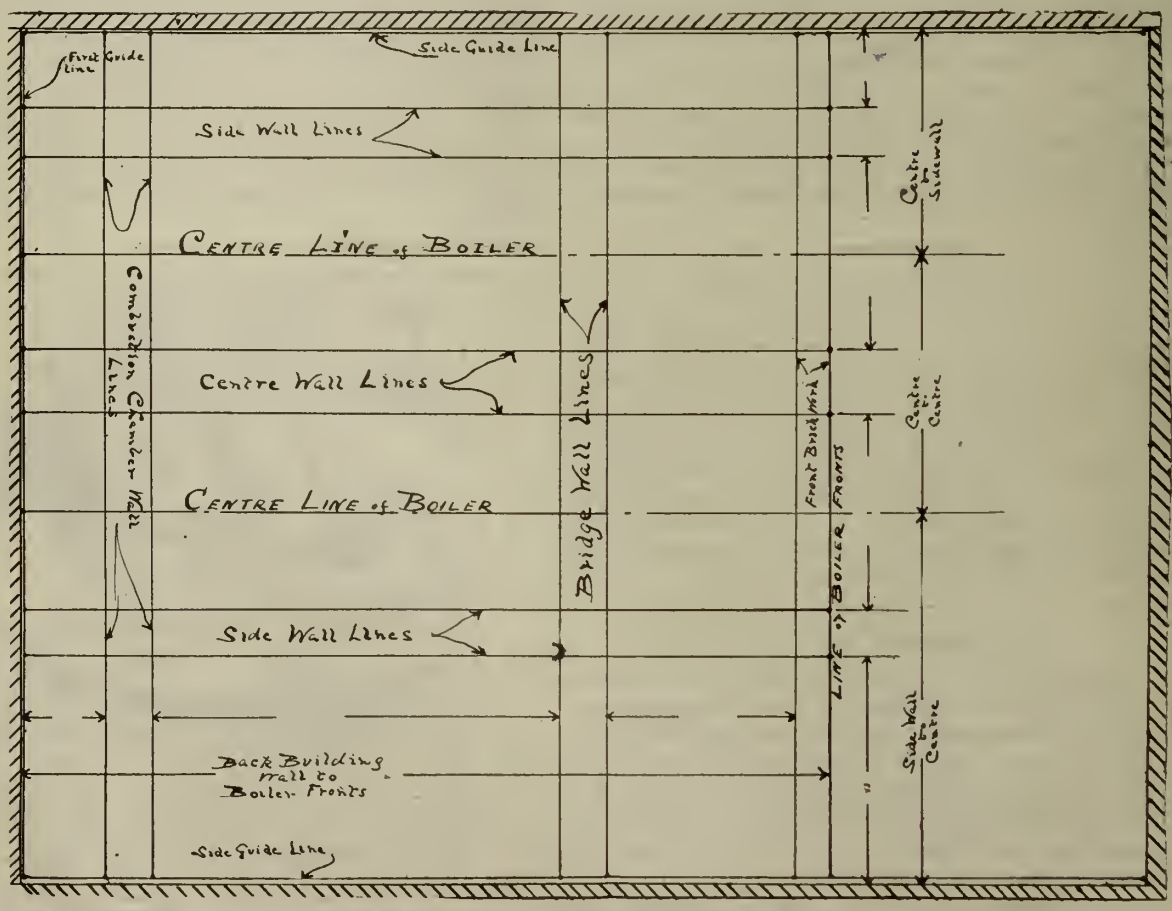
The Preliminary Steps

We will take for an example the installation of a new plant. Installing additional machinery in a plant already in operation has its difficulties, but on the other hand, it is somewhat simplified by the fact that there are well-defined leading marks such as lines of shafting, steam pipes, and so on, to aid in the location of the new foundations.

Let us assume that you have been called on to instal two horizontal return tube suspended boilers, 72 inches diameter by 18 feet long, and a cross-compound horizontal engine, with jet condenser, and the feed pumps, heater, etc., in connection therewith. Remember, the size of the installation really does not make any difference in the procedure, but only in the amount of labor. A 5 horsepower engine requires a boiler, steam pipe, feed arrangements, and a foundation to stand on; and a 5,000 horsepower engine requires the same things, but more of them. This much may be granted.

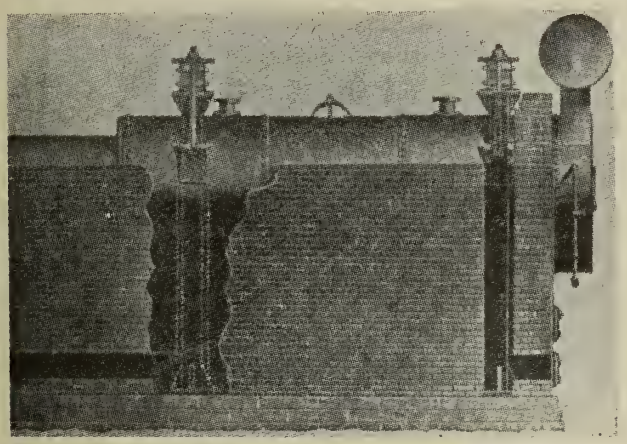
Now one advantage of the new installation is that in the majority of cases the layout, or the leading points of the layout, are determined before the first shovelful of earth is removed. Secondly, the field is clear, there being nothing in the way of bringing stuff in. In making additions to old plants, where very often adequate consideration has not been given to the possibilities of the future, many difficulties are encountered in handling heavy pieces of machinery in confined spaces. However, in this case these difficulties are not in evidence.

The first thing to be done is to procure blue prints of the general layout and detailed blue prints of the various foundations. Study these till the whole arrangement is thoroughly fixed in the mind's eye, and then make sure that the power house building has been completed in accordance with the plans. Look at the arrangements of doors, stairways, etc., and see if it is the best arrange-



LAYING OUT FLOOR FOR BOILER FOUNDATIONS.

ment in the light of operating problems. Right now is the time to observe one particular feature that will not only help you in erecting, but save time and money in future when repairs are necessary. I allude to means of handling heavy pieces, such as cylinder covers, flywheels, crank shafts, steam pipe, etc. If no crane is



SIDE ELEVATION OF SUSPENDED BOILER.

specified, then arrange to have eye-bolts secured to the roof, or an I-beam built into the walls on which you can put a small trolley to carry chain blocks or any other handy method which may suggest itself to your mind. It may cost a little at the time but it will save many times its cost.

For instance, the writer was in charge of a plant where the main header, 14 inches o.d. pipe, was supported on a frame about thirty feet above the boiler room floor. The roof beams were about the same height above the header. If an I-beam had been fitted longitudinally above the header at a reasonable height, taking a length down would have been governed by the time necessary to uncouple the flanges and lower away. Instead of this, hours were consumed in making a rigging to secure blocks to and the lowering and raising had to be done in several fleets, and on one occasion, at least, nearly resulted in a serious accident. In this plant an adequate travelling crane had been installed in the engine room, on the other side of the wall, and the installation of an I-beam trolley on the boiler room side would have been simple.

If the tour of inspection shows everything to be satisfactory, the next job will be to locate the foundations and get started on the job. Now, the foundation drawings from the makers of the boilers and engines will show the usual thickness of foundation that they put in, but remember, they probably know nothing of the nature of the ground that the foundation is to be put on. Different kinds of ground have different bearing powers, and whereas if you were erecting on rock you could build without any foundation; if the soil is soft blue clay, you must proportion the foundation to the bearing power. The following table shows the bearing power approximately of different kinds of ground:—

	Tons per square foot
Rock	200
Soft rock	18
Dry clay	4 to 6
Clay	2 to 4
Soft clay	1 to 2
Sand gravel	8 to 10
Sand	2 to 4
Alluvial	½ to 1

These values are not to be taken as exact, the value given for soft clay being on the high side. A good way to determine what the ground is like is to drive a pointed rod of iron down with a sledge, the resistance encountered in the driving giving a fair indication of the stability. Another point to be taken into account is that sometimes a foundation has to be made considerably deeper and heavier than the weight it has to support calls for. For instance, if an engine room floor is constructed with a basement 6 to 8 feet deep under it the foundation will have to extend from the basement floor to the engine room floor. Thus the weight thrown on the ground supporting the foundation is that much more than it would be if the engine room floor was laid on the ground.

However, as we are first concerned with the boiler foundations, there will be no necessity to figure on a floor level above ground. The maker will have given shipping weights or he may have given full information of weight of boiler bricked up, filled and all fittings on. If not, this weight must be determined. In the event of the ground being exceedingly soft, piling may be necessary, but this is a rare occurrence. Should it be so, it is better to call in outside help with the necessary equipment. In the case of blue clay, the best procedure is to make what architects call a raft, which is merely a large, solid slab of concrete. This concrete can be made of cheap material, using ashes instead of sand as a binder. It should be made of much larger area than the foundation and its purpose is to spread the weight over a large area to reduce the load per square foot to a minimum. For example, the writer had to make a foundation for a 50-ton railway track scale on this kind of soil. The scale manufacturer's erector was of the opinion that piling would be necessary. The bed of blue clay was of great depth, and piling would have been a very expensive proposition. Instead of this the excavation for the foundation was made 24 inches deeper than the plant called for. It was not practicable to make it wider on account of a shed covering the tracks. The form of the foundation was a number of piers supporting the bearing points of the scale, and these piers were joined together by a web 12 inches thick. The two feet deep excavation was filled with a mixture of broken brick, ashes and cement, on top of which the forms for the foundation itself were laid. The result was entirely successful, the scale erectors being very much pleased with the dry condition of the foundation through a prolonged spell of wet weather. However, suppose that the ground we have to deal with in the hypothetical case we are handling is of dry clay or sand gravel, with a bearing strength of four tons to the square foot. Let us first find out what weight we have to support.

The weight of a boiler 72 inches diameter by 18 feet long, complete with front and fittings but without water, is 25,000 lbs. roughly. The water capacity will be the volume of the boiler less the volume of the tubes. The boiler will never be full when working, but will be filled on many occasions for testing, etc. There are 72 4-inch diameter tubes in a 72-inch boiler. Their volume will be $4 \div 12 \times 4 \div 12 \times .7854 \times 72 \times 18$ and this subtracted from the volume of the boiler and multiplied by 62½ will give the weight of water in pounds. We have, then

$\{(6 \times 6 \times .7854 \times 18) - (4 \div 12 \times 4 \div 12 \times .7854 \times 18 \times 72)\} 62.5 =$ 24,812.5 pounds approximately.

The weight of boiler fittings and contents will therefore be 25,000+24,812=49,812, say 50,000 pounds. This is a suspended boiler so that this is the weight to be borne by the steel supporting columns. The walls for the setting will be with this size of boiler 18 inches wide and the foundation will be at least 2 inches wider.

We will have two brick walls 18 inches wide by about 22 feet long, and anywhere from eight to ten feet high, according to the height the boiler is set above the grate bars. The centre wall between the boilers may be wider on account of having the two supporting columns set in it, or perhaps the supporting columns in the centre will be heavy enough to carry the weight of the two halves, and the dividing wall remain the same. With suspended boilers the wall has no weight to support, and is there purely as an airtight casing. Supposing we allow a two-foot wall in between. Now, the back wall will stretch

right across the rear of the boilers, and be the same thickness and height as the side walls, so its length will be 1.5+6+2+6+1.5=17 feet. The bridge wall has to carry half the weight of the fire bars, the other half being carried on the two side walls or by brickwork across the front. The weight of a brick wall will be roughly about 125 lbs. to the cubic foot. Take a side wall first, we will have 1.5×22×10=330 cubic feet. 330×125=41,250 lbs. Our foundation is 20 inches wide and 20 feet long, that gives 1.66×20=33 square feet. That gives a pressure of only 1,250 lbs. per square foot, and the ground is good for four tons at least. Now the weight of the boilers is to be concentrated on six points, or if separate supporting columns are used in the centre, eight points. However, the columns in the centre will be adjacent to one another, so that the weight will really be concentrated at one point on the ground. We have, therefore, on each of the outside columns, 50,000÷4=12,500 lbs., the remaining 50,000 lbs. being supported on the two or four inside columns as the case may be.

That is, on each supporting point in the outside foundation the weight would be 12,500 lbs., while the two inside points would be supporting 25,000 lbs. each. These columns will be fitted with a foot of cast iron or steel with an area of 1½ to 2 square feet for the outer columns, while the inner ones, if designed as single columns, will have a proportionately larger shoe, or if each boiler has its own columns, the two shoes can be made to cover the width of the centre foundation.

The depth of the foundation will be governed by the probable depth of the frost line and will vary with locality. However, about three feet is a usual allowance. The crushing strength of good concrete is about 600 lbs. per square inch. On the outside columns we have a weight of 12,500 lbs. Dividing 600 into 12,500 gives a little over 20 square inches as being the necessary area of concrete. This is well within the proportions we have, so there is no need to bother as to concrete strength immediately under the column, and this weight will be distributed over a much larger area of ground by the concrete foundation. The same applies to the inside supporting columns so we are now in a position to lay out the ground and get the forms fixed up.

Locating Foundations

The first thing you require is a definite line to work from. You will have four bare walls and a rough, uneven floor. You want to determine the ground level, and for this you must turn to your building plans. This will show you the depth of foundation of the building and the relation of the top of foundation to the level of the ground. Therefore you take the foundation top as a point to measure from and it will usually be found to correspond with the ground level. Drive a stake into the ground or a nail into the foundation at the required level and attach one end of a line to this stake or nail. Now run this line along the wall parallel to the foundation to a second stake or nail and you have a base line established to work from. Take your subsequent distances from this line, and not from walls which may be two to six inches off the straight if of any great length. From this line run a second line at right angles, (squaring it off with a three-foot steel square), along the corresponding wall, and then you have the lines necessary for cross measurements. Run both these lines at a definite distance from the wall, and do not neglect to allow for this distance when making measurements.

The foundation plan will show the centre lines of the two boilers, their distance from each other, and the distance from the wall to the first centre line, and the second centre line to the other wall; the distance from the wall to the back boiler wall face, thickness of wall, combustion chamber space, length of boiler, and an overall dimension from the building wall to the boiler front. With these you can proceed to mark out the excavations for the foundation forms.

A word about measuring. Where the distances to be measured exceed fifteen feet use a steel tape, long enough to obtain the whole measurement in one reading. Measure along lines that have been squared off, and are straight, because if the tape is not held in a straight line, the measurement will be incorrect. The error will vary according to the length. Measurements taken with a short tape or a straightedge, that has to be moved along in stages, are almost sure to be out. Of course, for preliminary measurements to determine the excavation lines, accuracy is not essential, that is extreme accuracy.

First of all measure from your side line, along the back wall line the distance to the first boiler centre line. Drive a stake or nail here. Measure from that to centre line of second boiler. Then measure along the side line the overall dimension from back wall to boiler front, and mark it. Now measure from the other end of your back line along the opposite side of the building the overall dimension again, taking care that your tape is at right angles to the back line. The best way to be sure of this is to run a line first and square it off. Having got the two points on each side, stretch a line between them, and that is the line of your boiler fronts. Measure off on this line your two centre line points, and run lines from them to join the centre line marks on the back line. You now have your boiler front, and boiler centre lines accurately located.

From the front line of measure back along the centre lines to locate the front side of the bridge walls, thickness of walls, from back of bridge wall to front of back wall and thickness of wall. Place stakes at these points, and then measure on your front and back lines from the centre lines to the faces of the side and centre walls, and run lines from the front boiler line to back wall line to locate these. On the outside wall lines locate again the bridge and back wall lines, and run cross lines joining them. You now have your foundation completely laid out.

THE Mueller Co., of Port Huron and Sarnia, get out a house organ entitled "Mueller International News." Some of the items seem to indicate that the editor has a regular "stay for supper" acquaintance with his readers, to wit:

> "Hank Robertson was seen with a girl at the Free Methodist Church recently. It is claimed that he knocked three milk bottles over as he left her front porch that night."

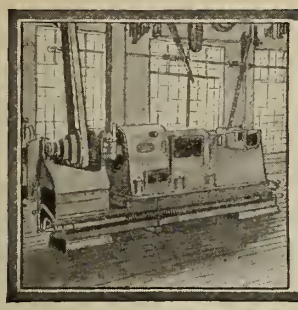
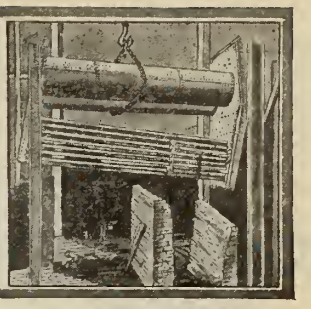
Signs of the Times.



NEW POWER PLANT EQUIPMENT

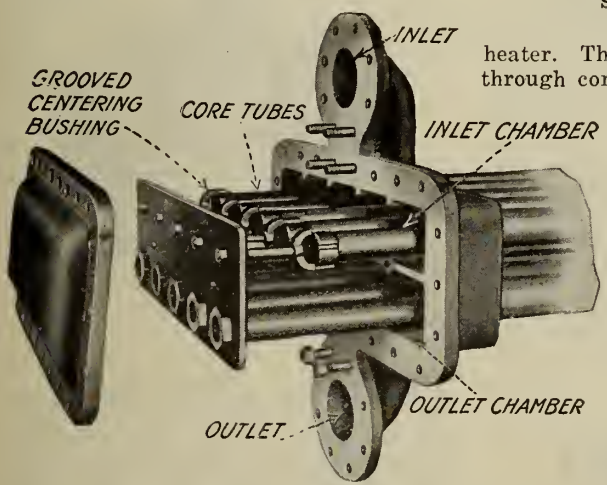


THE DRAVO SUPERHEATER

In designing apparatus to superheat steam, the main objects are: simplicity, efficiency and ruggedness. It should also be readily accessible for inspection and cleaning.

These objects have all been carefully considered by the Superheater and Engineering Co., of New York, in the Dravo superheaters, the headers of which are always outside the gases of combustion and are generously dimensioned steel castings or else extra heavy pipe, as is dictated by conditions.

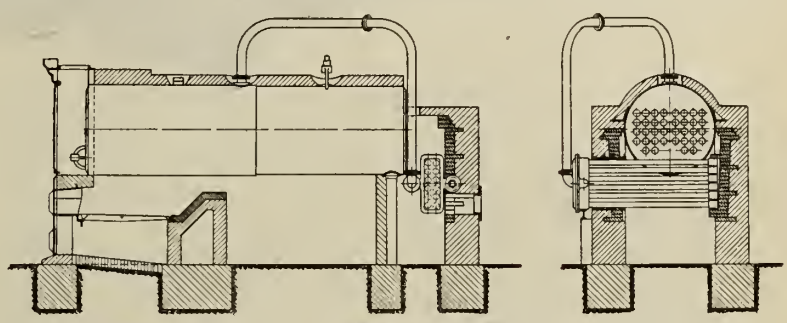
The tubing is seamless drawn steel tubes of suitable gauge which are expanded and flared into the headers. The openings in the headers required for expanding the tubes, are closed by means of closures made of machine steel with bolts threaded clear through and peened over. These are secured by tripod crabs and points made airtight by asbestos gaskets woven over copper netting, the gasket being placed in a pocket where it cannot blow out.



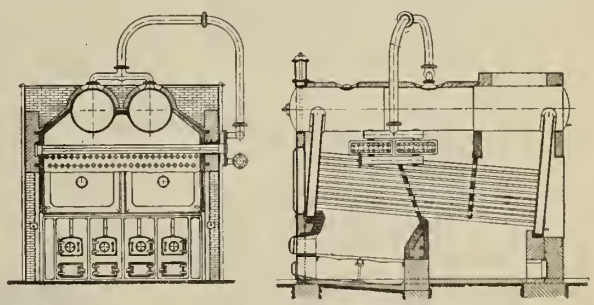
MAIN HEADER WITH COVER REMOVED AND CORE TUBES DRAWN.

The opposite ends of each two tubes are expanded and flared into cast steel connecting pieces or return bends. The openings in these castings are closed by key caps, which make a taper metal to metal joint and which the steam pressure tends to make tighter.

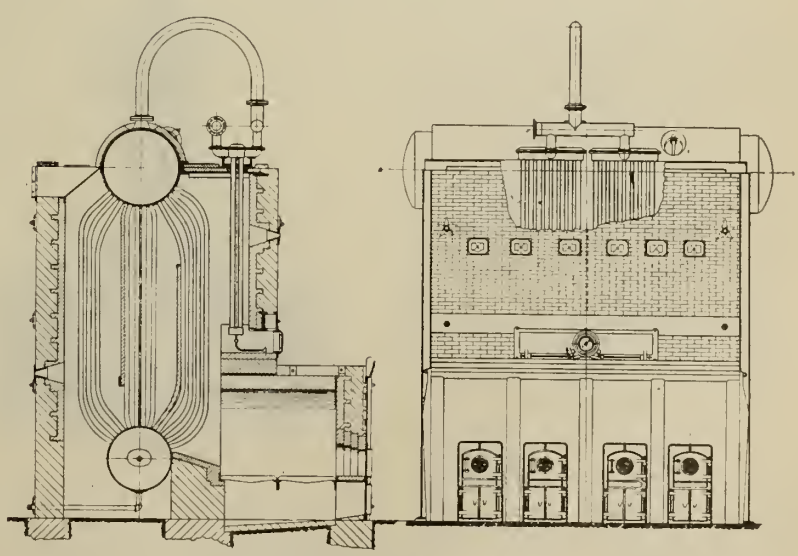
In order to efficiently heat a poor conducting medium like steam, and to do it quickly, for it is in the superheater but a short time, the steam must be brought intimately into contact with the tubes either by subdividing, filming or agitating it. Subdividing is usually done by using a number of small tubes, while filming is accomplished by means of a core within each tube, the steam passing through a comparatively small annular space. Agitating the steam as it passes through the superheater is the method employed in the Dravo superheater. The steam enters the apparatus through core pipes and through grooved bushings, which are used to secure and centre said core pipes. The core pipes are perforated and the steam which enters them is jetted through the perforations against the hot tube surfaces. It thus enters the annular space formed by the core pipes and tubes, in increasing quantity and the core pipes are decreased in size in the direction of the steam flow so that the resulting annular space is



SUPERHEATER APPLIED TO HORIZONTAL RETURN TUBULAR BOILER.



SUPERHEATER APPLIED TO WATER TUBE BOILER WITH THREE-PASS BAFFLING.

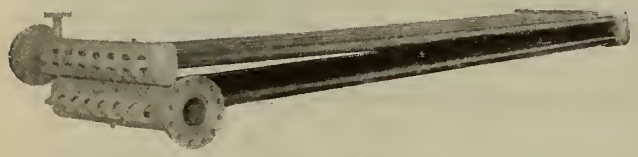


SUPERHEATER APPLIED TO ERIE CITY WATER TUBE BOILER.

increased, thereby lessening the friction in the superheater.

The method of agitating the steam has been found to be most efficient, and the lessening of friction has made the drop in pressure very small.

The comparatively few tubes in the



SINGLE SECTION OF SUPERHEATER.

TWO-SECTION SUPERHEATER SHOWING ARRANGEMENT.

Dravo superheater and their spacing offer little resistance to the passage of the gases through the boiler or its setting, thus making a drop in draft pressure due to installing the superheater almost negligible.

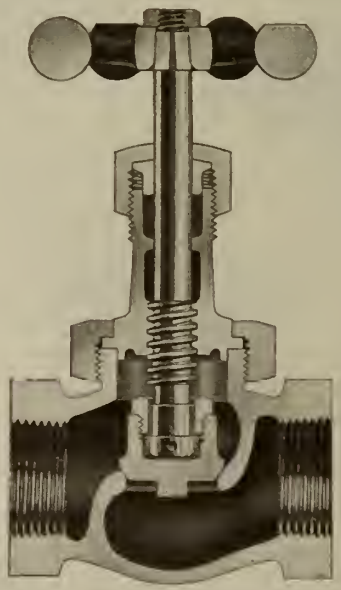
With the efficiency obtained by the agitating principle, the accessibility of parts, the simplicity of arrangement, the ease of cleaning, both inside and outside, and the materials used, make good the claims of the Dravo superheater to being efficient, accessible, simple and rugged. This equipment is adapted for installation in any type of boiler setting. The illustrations show several different types of boiler settings all fitted with the superheater.

JENKINS' NEW REGRINDING VALVES

The attention of the trade is called to two new types of high duty valves that have recently been designed and placed on the market by Jenkins Bros., of Montreal. This addition to the Jenkins line has resulted from the demand in certain quarters—particularly marine and shipbuilding—for an efficient regrinding valve. Both of these valves are designed to meet all the exacting requirements of the engineering trades and are being manufactured in various styles of globe, angle, horizontal and check.

The "Reliance" has been designed for a working steam pressure of 200 pounds per square inch. The body and bonnet are made of the very best naval bronze, assuring satisfactory service under severe working conditions. The naval bronze spindle is accurately machined to limit gauges, insuring perfect fit, ease of operation, and interchangeability. The lower end of the spindle is provided with an extra heavy collar that facilitates the regrinding of the valve seat. The disc is of substantial dimensions, having a radial face where it fits the seat in the body. The stuffing box is designed for high efficiency; it is fitted with a metal gland or follower and packed with special asbestos rings of such durability that they will not require renewing for several years. Packing may be renewed while the valve is under pressure and wide open. This is accomplished by the lock nut forming a seat against the lower side of the bonnet, thus shutting off the steam or water from the stuffing box. This feature also prevents the rattling of the disc. Ends of the valves are tapped with standard pipe threads.

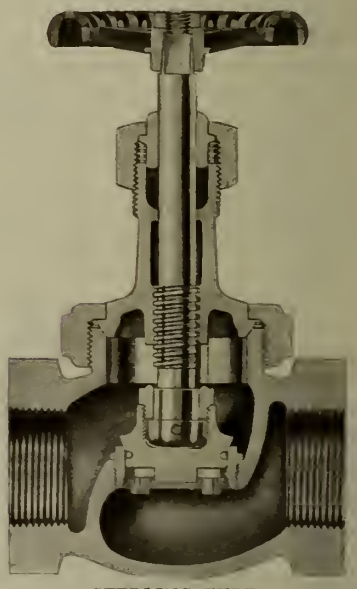
The "Sterling" type is of extra heavy design and suitable for a working pressure of 300 pounds per sq. in. These valves are subjected to a 800 pound hydraulic test before leaving the factory. They are similar in outward appearance to the "Reliance" valve, but the interior construction is varied to meet the added requirements of the higher pressure. The bonnet is fitted to the body by means of a ball joint. The slotted union nut permits the joint to be tightened by means of a spanner wrench, or a hardwood block and hammer. The disc in this valve is designed to minimize the cutting of the valve seat from the wire drawing of the steam. The extension below the main valve fits loosely in the valve port and holds back the steam and particles of scale until the valve is partly open, thereby preventing cutting action. The stuffing box is on the same lines as that of the "Reliance," but with a slight change in the shape of the gland or follower.



RELIANCE TYPE OF VALVE

NEW CONTRACT

The D. W. Griffith Company of New York city has recently given a contract to the Talbot Engineering Corporation of New York, for a complete plant for the operation of their motion picture studios. Owing to the immediate requirements it will be necessary to install a temporary plant while the permanent units are being built. It is interesting to note that the shop tests of the temporary boilers were made under the supervision of Roderick MacLeay, steam engineer of the Montreal General Tool Company, the Canadian company which is associated with the Talbot Engineering Corporation. The temporary installation will consist of two 100-horsepower type "T" Talbot boilers, one 11 x 25 x 14 Cross Compound Ball engine, one 14 x 16 Simple Straightline engine, and one 12 x 15 Ames Vim Horizontal Automatic engine. The temporary plant will operate non-condenser. Both the oil and feed pumps will be felt-driven triplex pumps. The temporary installation will be operated in a temporary building until the complete Talbot power plant is installed in the permanent power house. The permanent Talbot plant will consist of four 150 H.P. type "I" boilers, two 200 H.P. type "K" Uniflow engines direct connected to two Western Electric Co. direct current 150 K.W. generators, and one 100 H.P. Talbot type "G" engine direct connected to a 60 K.W. alternating current generator operating at 400 R.P.M. The engines are all of the four cylinder marine type mounted on cast iron frames or bed plates, which will carry both the engine and the generator. The engines will be connected to the generators with a flexible coupling. The plant will be condensing, using two 300-H.P. Talbot steel condensers. Storage batteries of large capacity will be comfined with the electric generators to steady the intermittent load required in the motion picture business.



STERLING TYPE.

The Operators' Point of View

RE GRADED CERTIFICATES

The Editor,—Referring to the Act, grading certificates, it seems to me that the statement in heavy type, page 435, gives very little encouragement to engineers not in charge to try and improve themselves, or obtain a higher position or certificate.

Any engineer in charge of a plant of 150 B.h.p. or over is entitled, if he holds a 1919 certificate, to continue until he changes his position.

This means that all engineers who are graded 2nd or 3rd class for 1920 who are not in charge, will never get in charge of a plant of over 150 B.h.p. unless some charge hand dies, quits his job, or a new plant starts up.

If this ruling is correct, it simply makes the Act a farce. On page 432 it states that any person who is in charge of a plant of unlimited capacity (i.e., 300 B.h.p. and over I suppose) must hold a first-class certificate. It also states in Section 15a that every person who operates as an engineer in charge without the certificate required by this Act, etc., is guilty of a contravention, etc., yet those who happen to be in charge for 1919 are permitted to continue, and some of our best engineers who have not been fortunate enough to get a charge job can remain just where they are to-day. Otherwise I think the Act is splendid, but let the best men have the charge jobs.

If a person takes an interest in the profession, studies hard, improves his knowledge and obtains a first-class certificate of competency, then for the sake of efficiency let him have a chance at a good job.

I would suggest that all engineers in charge who receive a grade lower than what the Act calls for should be given a provisional certificate to continue not more than one year, sit for an examination, and if they fail let a qualified man have the job.

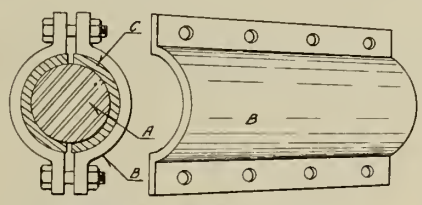
I would like to hear other readers' views on this matter.

JUSTICE.

EMERGENCY SHAFT COUPLING

Some time ago in fitting up a cheese factory some miles from any city, the discovery was made, somewhat late along on the job, that two 2-inch shaft couplings had not been sent along with the other material. The machines were all set and the hangers up ready for the shafting. There was a fairly good blacksmith in the village near the factory, so the erectors got him to split two pieces of 2-inch pipe, cutting a strip ¾ inch wide out of the length of the pipes. The pipe was 10 inches long. He also made two clamps for each pipe from heavy iron 10 inches long and big enough to fit over the pipe. He was just a little over three hours in cutting the pipes and making the clamps.

In Fig. 1, A is the shaft, B the clamps, and C the cut pipe. Fig. 2 shows one of the clamps. The whole outfit was put together as in Fig. 1, the



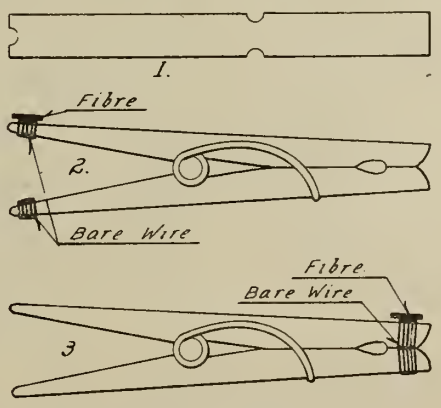
EMERGENCY SHAFT COUPLING

bolts in the clamps being drawn up tight, the shaft was lined and the outfit started. The couplings held on fine and ran for some months before the regular ones were put on. After the couplings had been tried out, strips of old canvas were wrapped around them and wired on to prevent the possibility of any oiler being caught by the bolt heads or ends, or cut by the corners of the clamps.

JOHN JAMES.

CONTACT CLIPS

For making either self-opening or self-closing electric contacts for use in wiring or testing, a dozen spring clothes



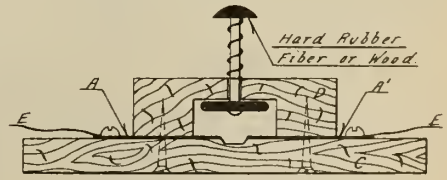
CONTACT CLIPS

pins with a little sheet rubber or sheet fibre and some bare wire will make a dozen contacts. Remove one of the wooden pieces from the pin, and around one end of the other wooden piece wind some bare copper wire to provide a contact surface. Then cut a piece of the sheet rubber or fibre to fit behind this bare wire to insulate it from the wall. And fasten to the wall this wooden piece, together with its wire spring and the piece of rubber or fibre. The fastening may be done by using two styles (or even one can be made to do) preferably just a little narrower than the wood of the pin, so that shallow notches are required in the edge of the pin and these will prevent end movement. If screws are used do not bore the pins for them as the wood may split. Fig. 1 shows the wood notched for three screws, one at the thin end and one at each side toward the other end. Having these in place wind bare wire onto the other wooden piece and to correspond with that wound on the first piece, then insert it into its place in the wire spring. Fig. 2 shows a self-opening contact. Fig. 3 shows a self-closing contact. In making Fig. 3 it sometimes may be necessary to trim a little wood off the humps to give the wire a hold, or if this will not let the wires come together when wound, place some sheet fibre into the hollows and then wind the wire on.

If the bare wire used consist of some of the end of the piece of bell wire being used in the circuit itself, but from which the insulation has been removed just there, this method of winding will avoid the necessity of making two wire joints later to connect the contacts with the circuit wire.—J. E. M.

QUICK-ACTING SWITCH

The home-made quick-acting electric switch shown may interest a number of readers. The face C is made from a piece of wood 6 inches long and 3 inches wide and ⅞ of an inch thick. The block D is 4 inches long, 3 inches wide, and



ELECTRIC CONTACT SWITCH

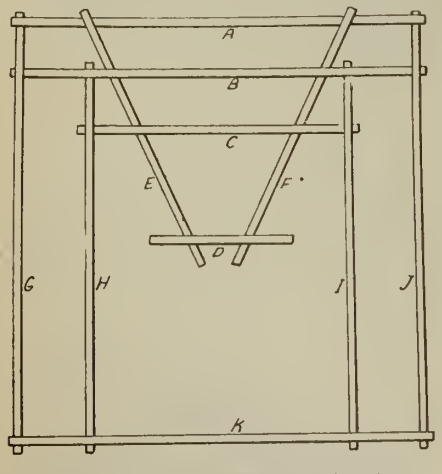
1½ inches thick. The blocks are planed, sandpapered, and given two coats of shellac. The terminals AA' are strips of copper, to which are attached the light wires E. A piece of copper is rounded at the ends and a piece of heavy

wire is riveted into it; on the other end of the wire a push piece can be riveted, as at B. A light piece of wire spring is used to hold the switch open; the blocks are fastened together as shown. A push down on the knob B completes the circuit on this single-pole switch; this switch is instantaneous. It is not difficult to make, and a locking clip can be added, if desired, to hold the circuit closed with another few minutes' work.

J. E. M.

REMOVING REFUSE AROUND THE POWER PLANT

Wheelbarrows, such as are used for wheeling coal in or those used by contractors for wheeling heavy material in, are a slow rig to wheel light bulky stuff on, for one cannot pile on nearly so much stuff as he could wheel away at a time. The sketch I enclose rudely shows how I made a rack for a wheelbarrow to be used in wheeling light refuse material which, by the way, was coarse enough to not fall through. No dimensions are given as these would differ with different makes of barrows and also the outside dimensions of the rack are a matter of choice and in consideration of the class of material proposed to be wheeled. Pieces E and F are laid into the front corners of the barrow and extend forward diagonally. If necessary they are weighted down on the inner ends to hold them in place until other parts are attached. D is fastened to them and is just long enough that its ends brace against the sides of the barrow. K lies across the handles but not close enough to be uncomfortably in the way. A, G and J are then attached as shown, A passing under E and F. B is placed under G and J and above E and F and shoved up tight to E and F and fastened there. H and I are then placed below B and K, and C is placed under them and above E and F, and shoved up tight to E and F. C should be left plenty long and can be shortened later



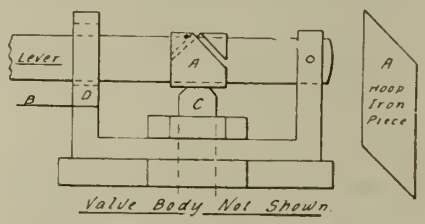
FRAME FOR WHEELBARROW

if desired. C, H and I are then adjusted to what appears to be the best position and fastened there, and C trimmed if desired. This completes the rack, which may be lifted off at any time. To hold it in position when in use, it depends on the fit of E F into the corners of the barrow and on the fit of D against the barrow sides. The weight of itself and its load holds it down. I used wooden slots 1 by 1½. Other material could be used. More pieces could be put in if required. The manner in which A, B and C are put in maintains the slope of E and F.

J. E. McCORMACK

REPAIRS TO SAFETY VALVE

Owing to the effective length of the combined valve-head and valve-stem having become reduced by wear and by regrinding the lever arm of a ball and lever safety valve sloped downwards towards it outer end until the ball was inclined to keep slipping along the arm, thus increasing the pressure at which the valve would lift to let the steam escape. At first I wired X each side of the staple in the ball to a side of the guide (D) through which the arm passes. These wires (B) were always taut, and I thought they interfered with the free action of the valve. As a remedy I took a piece of hoop iron, 1-16th inch thick or more; heated it to redness and allowed it to cool slowly, thus rendering it less brittle; then cut a piece (A), with oblique ends and the length of each side nearly equal to the distance

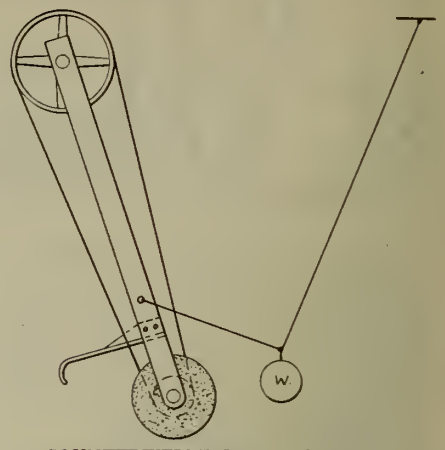


SAFETY VALVE REPAIR

around the lever arm at a point just above the valve-stem, and wrapped this around the arm as indicated in the sketch. I left the aforementioned wires (B) on as they had been, but they now remained slack. Had there been more slope to the arm it would have been necessary to use thicker iron or else slip a narrow strip, not wider than the arm was thick, through underneath the arm and between it and the hoop iron piece, but as it was this one piece of hoop iron did the trick alone. A little care should be taken to see that the hoop iron does not be uneven enough to bring the pressure to bear toward one or the other side of the valve-stem instead of over the centre, and when next firing up one should watch both the valve and the steam gauge to see that they correspond as before. In making the repair care should be taken to see that no chips or filing attach themselves to the valve-stem or get a chance to work into any part of the valve mechanism.—J. E. M.

COUNTERWEIGHING SWING FRAME

In some factories and mills swing machines resembling that in the sketch are in use and it is desirable to have them held back out of the way when out of the work. A weight attached to the frame by a rope running over a pulley is common practice, but possesses no buffer effect at the end of the return stroke. It rather stops with a jerk. An operator here rigged the device in the sketch and it was soon copied in another



COUNTERWEIGHTING A GRINDER

plant by another operator. The weight W, hangs on a rope attached to the frame and to hook behind and higher up. The rope must be slack enough to let the machine swing well ahead without the rope pulling into near a straight line. The principle is that the full of W varies with the size of the angles assumed by the rope. The pounds weight required in W, the slack in the rope and the distance of W from the frame must be determined experimentally in individual cases. The first two factors may vary within rather wide limits, the location of W on the rope being determined later by experiment as it is in this adjustment that the chief virtue exists.—J. E. M.

COMMERCIAL AVIATION

With the prospect of peace-time conditions, aeronautical engineers are devoting their time and energies to perfecting forms of aircraft that will be reasonably safe, and pilots are being more carefully trained in managing airships of various kinds. The British Government has recently decided to offer prizes in a competition to develop safer airplanes. An appropriation of $320,000 has been made for this purpose, and the prizes will be distributed among producers of large airplanes, small airplanes, and sea planes.

Regular trips are made from Milan to Rome, from Milan to Padua, and from Rome to Naples. The Rome-Milan trip occupies three and one-half hours by airplane, whereas the same journey by train takes about eighteen hours. For this service an eight-passenger airplane is used, fitted with an inclosed cabin, electrically heated and lighted and provided with arm chairs. Five hundred pounds of mail are carried on these machines in addition to the passengers. Daily trips are made across the English Channel, and during the Peace Conference Mr. Bonar Law traveled regularly from London to Paris by airplane. In Paris, regular ascents are made daily, carrying passengers, and in London during three days of Easter week the Handley-Page Company carried 827 sightseers over the city.

THE VALVE ENGINEERING CO.

A recent development in the power plant supply field is seen in the Valve Engineering Co., which has opened offices at 160 King Street W. for the sale of valves of all kinds. Mr. M. J. Keane, the proprietor, is well known in the steam specialty business, having been for seven years manager of the valve and steam goods department of the Canadian Fairbanks-Morse Co., Toronto. Before his connection with the above firm, Mr. Keane was with the Walworth Mfg. Co., Boston, as salesman, and also with the Pratt & Coady Calve Co., Hartford, Conn. Experience of this nature has well qualified him for the giving of

M. J. KEANE
Who has started the Valve Engineering Co., King St. W., Toronto.

engineering service in connection with the specialties he is handling, a long felt want in the power plant field.

Agencies for a number of very good lines have been secured. Penberthy valves and other apparatus will be handled; Witwyte high pressure packing and jointing and Pennsylvania flexible metallic tubing will also be a special line. Witwyte high pressure jointing is used for steam, hydraulic, gas engine, motor car and other joints, and is intended for superheated steam of all pressures. The Pennsylvania line of metal hose is well known, and in demand wherever metal hose which will stand severe usage is necessary.

In keeping with the idea of service to the engineering public, all lines handled by Mr. Keane will be kept in stock at all times, ensuring prompt delivery, instead of delay, while woods are being sent or made at the factory.

NEW FACTORY OF YATES REFRACTORIES

In order to supply the constantly-increasing demand for furnace fire brick, the Gates Refractories, Ltd., have recently acquired a plant and property in Montreal East, and are now operating on a scale that will gradually meet the requirements of the trade. Until a few months ago J. W. Gates, the patentee of the bricks that are now being manufactured by this company, obtained his supply from old-established fire brick firms, but the growth of the business during the past year necessitated considerable more brick than could be furnished by outside companies. In view of this the original company was reorganized and additional capital secured for the further extension of their activities, and likewise the acquisition or construction of a plant for the production of bricks for their own special requirements. They will likewise be in a position to supply all special shaped high-grade fire brick for every industrial purpose. The plant acquired is located about seven miles from the centre of the city, and was formerly occupied by the Art Furniture Company.

The buildings are of two-storey brick construction, with about 12,000 feet of floor space. Two large crushers, one dry and one wet, have been installed with the necessary conveyors fer carrying the crushed and ground clay from the dry to the wet machine. The storage of the materials and the molding operations are carried out in this department, and to the rear of this building a drying room, 60 by 60 feet, has been erected and fully equipped. The floor of this section is of tile, under which the steam piping is located for the drying of the bricks after they come from the molds. To one side of this addition are located the baking and burning kilns. At present there are two in operation, one of 50 tons and one of 60 tons capacity. Two others of 60 tons capacity each will be completed and in operation before the close of the year. Eventually the kilns and the drying department will be under the one roof. The present output of the factory is about 300 tons per month, but this will probably be doubled within the next few months. Efficiency tests have been made at the McGill University on these bricks, and the fusing point has been determined, officially, at approximately 1750 degrees C., or 3200 degrees F.

(Canadian Representative)

one side of the plant and there are also docking facilities a short distance from the works for the shipment of materials or product by lake or ocean vessels. The aims of this company are to specialize in contracting for power plant brickwork, also manufacture all kinds of special shapes of fire brick for boiler settings and all types of furnaces.

CATALOGUES

The Sanford-Riley Stoker Co. announces the appointment of Mr. M. G. Brennan as district engineer in the Western territory and Mr. W. Mather as district engineer in the East.

The International Chemical Co., Toronto, Ont., have issued three pamphlets descriptive of "Protecto" for boilers, International Gear Coating for all forms of gear drives, and International Soluble Cutting Oil for machine shop use.

Clinkers Conquered is the title of a booklet recently issued by Ernest Bernitz, Inc., Boston, Mass. Its purpose is to acquaint the engineering public with the Bernitz method of furnace construction.

The Sarco Company, Inc., New York, have issued a new bulletin on their steam traps. It is descriptive of this now well-known power plant accessory.

The Esterline Co., Indianapolis, have issued a publication entitled, Typical Graphic Records. As the title indicates, this publication gives a large number of typical charts taken by Esterline graphic meters on various industrial operations. The machine shop rolling mill and other steel working industries are particularly prominent in the number of charts displayed. In the eighteen years in which the company has been engaged in the graphic recording instrument business they have collected quite an interesting series of characteristic curves, and many of them are reproduced in the publication under review.

The Bailey Meter Co., Cleveland, Ohio, have recently issued Bulletin No. 30, entitled, "Fluid Meters For Low Pressure Gas and Air." The meter described in this publication is ideal for the measurement of the flow of gases and air under low pressure, recording and integrating the rate of flow of gas and recording gas pressure.

The Canadian SKF Co., Ltd., Toronto, have issued Talk No. 4 on countershafts. The subject matter describes the advantages of self-aligning ball bearings for this class of work.

Getting New Plant.—The Acme Roofing Co., Walkerville, Ont., have sold their factory, and it is their intention to erect a new plant and install the most up-to-date roofing machinery and equipment. They are now receiving tenders on new machinery. Information as to the location of the new factory will be given out later.

CONDENSED ADVERTISEMENTS

COMBUSTION ENGINEER

WANTED—PRACTICAL BOILER ROOM Engineer in hand firing and familiar with various boilers and automatic stokers, who has made study of combustion and has some knowledge of instruments, to specialize under expert in efficient boiler operation. Must be keen and of pleasant manner to instruct, without antagonizing firemen who consider themselves proficient. Excellent prospects for the right man. Reply fully Box 152, Power House.

STEAM TURBINE DRIVEN TURBO BLOWER SET

with Condensing Plant for quick delivery from stock at very favorable price.

Steam Trap SARCO Goes Where Other Traps Can't Go

There are many points on your line where you should have a steam trap, but where there isn't room for a cumbersome bucket or float trap.

Leaving these points go untrapped is costing you money! For when live steam is carried through long lines of untrapped piping, there is useless radiation and waste of steam.

Stop that loss by installing the Steam Trap Sarco.

It is so small, so compact, that it can be installed without change of piping.

The Sarco requires no floor space because it becomes practically integral with the pipe system.

It requires no building up or pit digging. It can be installed at any angle. And you can install three Sarcos for the price of one float or bucket type.

Its capacity is guaranteed for any pressure up to 200 lbs.

Try the Steam Trap Sarco for 30 days without cost or obligation.

Send for booklet "J"

THE McDONOUGH DAMPER REGULATO

This Damper Regulator saves $300 per boiler annually in many plants. It will on ½-lb. variation regulate Dampers, Stoker Engines, Stoker Motors, Forced Draft Engines, Gas Supply to Boilers. We put in the Quality before we put on the name.

We install this Damper Regulator in your plant for 30 days' trial, free of cost to you.

THE FEED WATER REGULATOR

We know positively that this Feed Water Regulator does what other Regulators try to do—maintains a flow of water to your boilers at the exact rate it is being evaporated into steam, that means boilers give drier and more steam for less money than is possible with other Regulators.

Operation of the Feed Water Regulator

When the Regulator is installed, the lower ends of the expansion tubes are filled with water, the upper ends steam.

As the water falls or rises in the boiler it correspondingly falls or rises in the Regulator tubes causing them to expand or contract or regulate the opening of the feed valve to admit the proper quantity of feed water to meet the exact demand made on the boiler for steam.

The levers move the valve disc in a ratio of 5 to 1 over the amount of expansion or contraction of the tubes and the slighest change in the temperature of the tubes has an immediate effect in changing the position of the valve disc to the amount of opening desired in the feed valve.

In actual practice the feed water valve does not fully close while the boiler is steaming.

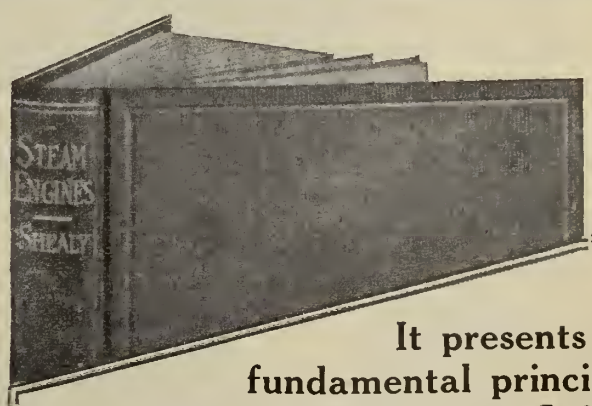
Get This Book



It presents the fundamental principles underlying the operation of the

STEAM ENGINE

The parts dealing with thermodynamic principles are particularly clear and practical.

The treatment of valve gears is especially complete because operating engineers find information on valve gear mechanism so valuable.

Tells about steam engine indicators and indicator diagrams and the proper way to use them.

Gives laws of heat engineering —a plain, straightforward, non-mathematical explanation of the laws of force, work, energy and heat.

And gives other special features too numerous to mention.

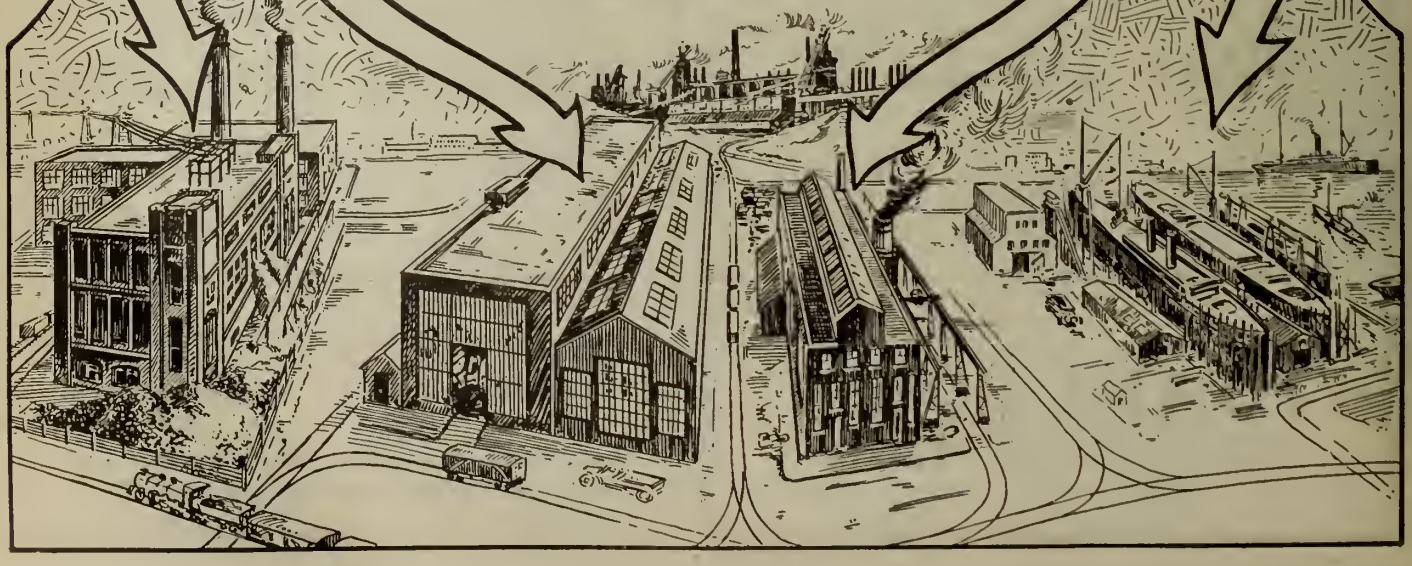
Thirty years' experience and dozens of practical men in your own line, stand ready to serve you. Let them! Subscribe for your paper to-day.

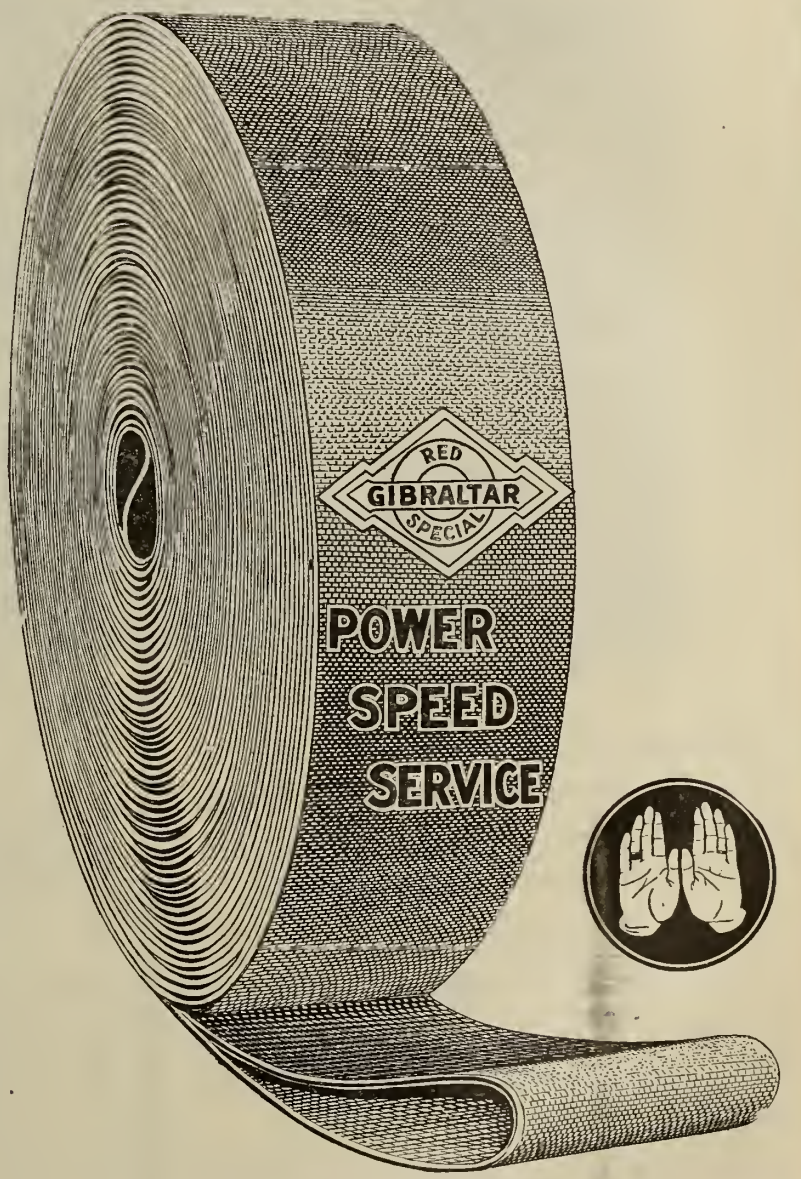
Men with selling problems will find a profitable tip in the statement made by a prominent manufacturer recently, "I use MacLean Publications because I am satisfied that papers with such a high standard of editorial excellence, MUST have an influential following."



DUNLOP

"Gibraltar RedSpecial" Belting

"THE ORIGINAL RED FRICTIONED-SURFACE RUBBER BELTING"



WHEN it's a question of unusual achievements in Beltdom, "Gibraltar RedSpecial" stands supreme.

As an effective means of trimming down "overhead" it is known far and wide.

This Red Frictioned-Surface Belt has dominated the field since its inception.

Without variation this belt has lived up to the exacting standard of service set by us when it was first introduced to belt buyers.

Having been tested and tried to the limit in all manner of places—and by thousands of users throughout the country from the Atlantic to the Pacific—"Gibraltar RedSpecial" will also secure you against the uncertainties which surround the use of "just-as-good" brands.

The price may be higher than that of "ordinary" belts, but the service is long and satisfactory in the extreme, as a multitude of long-time users will gladly testify.

With the Dunlop Unreserved Guarantee which goes with every belt, you should have no hesitation in making your next order read "Gibraltar RedSpecial."

You know the Dunlop reputation for square-dealing, too.

THE DEXTER VALVE RE-SEATING MACHINE

shown above is a simple, inexpensive and effective device, the use of which will save replacing your present costly valves with new ones.

This machine, without removing the valve from whatever position it might occupy, will re-cut the seat of any valve, thereby making it equal to new.

We stock these machines in various sizes and suited to all kinds, sizes and types of valves. Ask for Catalogue No. 5.

Are You Saving Fuel?

Get the Most out of Every Pound of Coal

Fuel Economy in Boiler Rooms

By A. R. Maujer and Charles H. Bromley of the Editorial Staff of Power

The new book that covers the broad question of fuel economy, including fuels, firing methods, furnace efficiency, etc.

It is written in simple, understandable style from the point of view of the man actually responsible for fuel saving. It is not a book of theory, but actual methods in use to-day. 308 pages. 98 illustrations, $2.75 net.

Steam Boilers

By Edward M. Shealy, B.S., Assistant Professor of Steam Engineering

A book that treats the operation of boilers in considerable detail, and specially written for the use of firemen and others in responsible charge of boiler rooms.

It covers fully and practically, boiler operation and equipment. It has useful material on efficient combustion and smoke prevention. 356 pages. 185 illustrations, $2.75 net.

Hea

By Edward M. Shealy, Assistant Professor of Steam Engineering

A book that is well adapted to the requirements of engineers and firemen who have had some experience with heat using machinery and understand its operation, but feel that they do not know enough of the laws of heat to take up advanced or special studies. 262 pages. 110 illustrations ..... $2.25 net

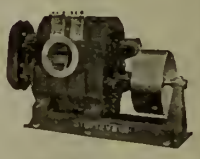
Medium Pressure Blower

VS-7 ENGINE
Single cylinder
Throttle automatic control

NOW STANDARDIZED

Now standardized in two types only, VS-7 and VS-8 (vertical, single cylinder). All others have been eliminated in order to supply the increasing demand for these two types.

Low Pressure Blower



High Pressure Blower

VS-7 and VS-8 differ only in method of lubrication. The former is one of gravity sight feed with automatic return oil pump, while the latter is of forced feed type. Both systems have their friends.

Both are sturdily built to withstand the most gruelling service. Designed to U.S. Navy specifications which fact attests to their supreme reliability under all conditions of service.

Volume Blower and Exhauster

Gasolene Generating Set

Used for direct connection to blowers, fans, generators and for independent power service, automatic or throttling. Specially prepared catalogue No. 239 goes into detail, is interesting and highly instructive—and yours for the asking.

OVER 1000 INDUSTRIALS USE

GOODYEAR
MADE IN CANADA
EXTRA POWER BELTING

ON RECORD in our offices alone are the names of over 1000 Canadian industrials who are satisfied users of Goodyear Extra Power Belting.

A vast hive of industry, giving employment to thousands upon thousands of men. Engaged in every form of industrial activity known in the Dominion. Turning out millions of dollars' worth of Canadian products every year.

What an overwhelming endorsement of Goodyear Extra Power Belting this is. Belts bought to fill every transmission requirement. Working under varied conditions. All required to deliver satisfaction. Think of the great power-saving because Extra Power Belting is flexible. It grips the pulleys and combats slipping. Greater production has almost invariably followed the use of Goodyear Extra Power.

Over a thousand trained engineers and superintendents cannot be misled. You cannot blind over a thousand purchasing agents. There must be—there is—something vital in the Goodyear Extra Power Belting story. Let us send a man trained by Goodyear in belting problems to talk it over with you. He will tell you about Extra Power as it applies to your plant. Should Extra Power not be suited to your needs, we would rather have your friendship than your order. Phone or write the nearest branch.

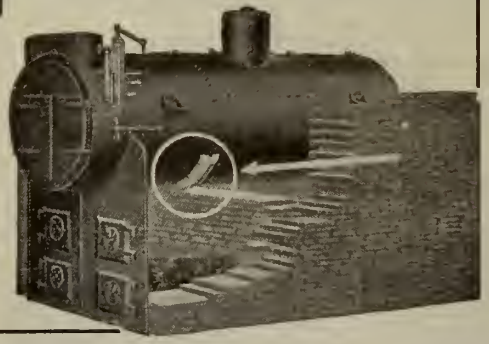
NATIONAL Boiler Girth Seam Protector

Protection means longer life and greater efficiency

If your Boiler is not Fire-cracked it eventually will be. Prevent this by putting on a National Boiler Protector. You will save cost in repairs and prolong life of the boiler. All new boilers should be protected. If your girth seam is giving you trouble at the present time, have the seam caulked up, attach one of these protectors and the seam will remain absolutely dry thereafter.



Guaranteed for one year. We make protectors for patches and all styles of boilers. For full particulars, write—

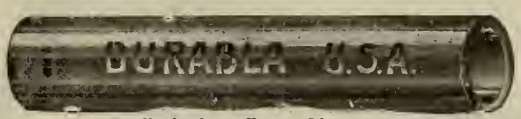
DURABLA
TRADE MARK REGISTERED

STRENGTH—GOODNESS—QUALITY



Etched on Every Glass

DURABLA HIGH PRESSURE GAUGE GLASS

The first test of the new American made DURABLA high-pressure gauge glass was to determine whether it possessed the elastic properties necessary to withstand sudden and radical changes of temperature.

DURABLA U.S.A. glass was immersed for two-minute periods in oil at a temperature of over 380 deg. F., then in water, at a temperature of 40 deg. F. This operation was repeated from 14 to 18 times on many lots of glass, and not one was in any way affected. No attempt was made to see how many times the glass would stand this severe test, the number of immersions given being considered ample proof that the glass possessed the necessary elasticity.

DURABLA U.S.A. gauge glasses are now ready for distribution in all standard sizes and are sold under the DURABLA guarantee.

A Complete, Practical Correspondence Course of Study in

Stationary Engineering

ONTARIO DEPARTMENT OF PUBLIC WORKS
STATIONARY ENGINEER'S CERTIFICATE
THIS IS TO CERTIFY THAT
SPECIMEN
IS ENTITLED UNDER THE ACT RESPECTING STATIONARY AND HOISTING ENGINEERS R.S.O. 1914 [illegible] TO OPERATE AND HAVE CHARGE OF A STATIONARY STEAM PLANT OF FIFTY HORSE POWER AND UNDER IN THE PROVINCE OF ONTARIO DURING THE YEAR 1919 UNLESS THIS CERTIFICATE IS SOONER REVOKED CANCELLED OR SUSPENDED
1919.
DATED AT TORONTO THIS [illegible]
NOTICE THE HOLDER OF THIS CERTIFICATE MUST KEEP POSTED UP IN THE ENGINE OR BOILER ROOM IN WHICH HE IS EMPLOYED

Let Us Show You How To Get This License FREE

We Trained Last Year 1000 Men for U.S. Government

Up-to-Date Stationary Engineers are in Demand

This modern course of study covers every branch of power-plant work, including Steam Engineering, Practical Mathematics and Electric Wiring—all the principles of practical electricity. The Course has been prepared by a staff of experts working under the personal supervision of Joseph G. Branch, B.S., M.E., author of many standard books and for many years Chief Engineer of the City of St. Louis and a member of the Examining Board of Engineers for that city. Although complete in every detail, the Course is written so simply and clearly that anyone can understand it. No useless theory—but all the straight **facts** you need to pass the Engineer's Examinations and hold down a good job. You can substitute **Mechanical Refrigeration** for **Electrical Wiring** at the same price for the course.

All Text Books Furnished FREE

Five text books, handsomely bound, printed in large, clear type on fine quality paper, are furnished absolutely FREE with this course. They are sent to you at once. You do not have to wait several weeks or months, you get **all** the books **immediately.** Besides the books you get all necessary stationery and envelopes for answering questions and making recitations. There are no extras of any kind.

We Assist Our Students in Getting Good Positions

THE COURSE YOU WANT IS HERE

Complete, Practical Correspondence Courses in

Electrical Engineering	*Power Plant Engineering*	*Drafting*	*Practical Mathematics*
Mechanical Engineering	*Power Plant Accounting*	*Drawing and Designing*	*Ingenieria Electrica* (Spanish Course)
Stationary Engineering	*Marine Engineering*	*Practical Chemistry*	*Mechanical Refrigeration*

Send for complete catalog, letters from students and list of positions secured

Special Offer—Mail Coupon Quick

The price of the course is extremely low and just now we are making a **special limited offer** to those who reply to this advertisement. This remarkable offer reduces the cost of the complete course to a **very low figure.** You will be astonished to find how little this tremendously valuable training will cost you. Mail coupon **at once for** full particulars and **special terms.**

FREE COUPON

Joseph G. Branch School of Engineering,
Dept. P, 542 S. Dearborn St., Chicago.

Without obligation please send me information how to get a Stationary Engineers' License and full information about your Course and Special Terms.

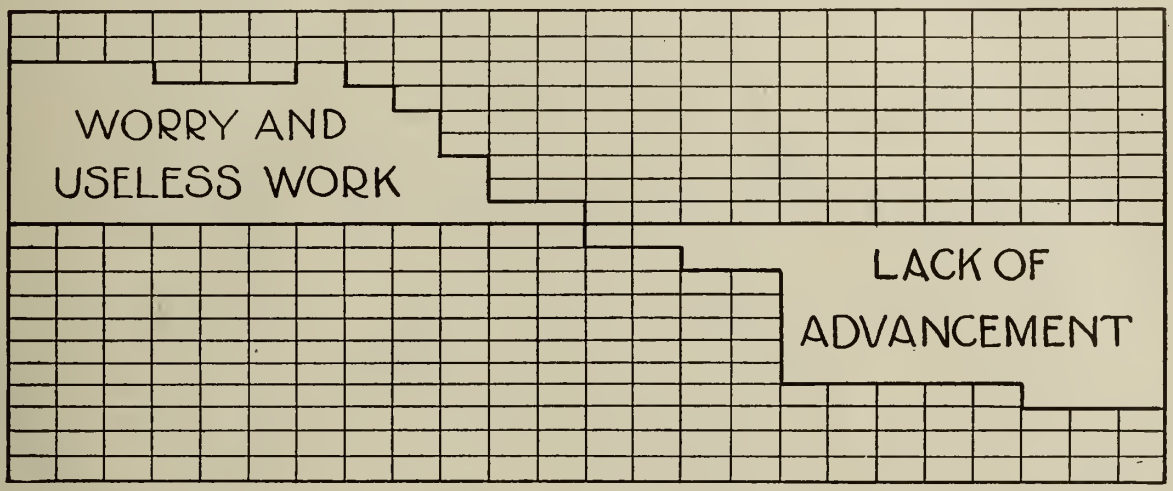
Let the C.A.S.E. Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

JEFFERSON

Underground

Take a trip underground—listen to the music of the pumps—"CHUG, CHUG, CHUG" — twenty-four hours a day, and you'll realize the importance of dependable unions. The failure of a single union might cause serious consequences involving loss of life and heavy damages.

JEFFERSON UNIONS will render perfect service as long as the pipe line holds out. Once you put a JEFFERSON on the line, you can say "Good-bye" forever to pipe line troubles.

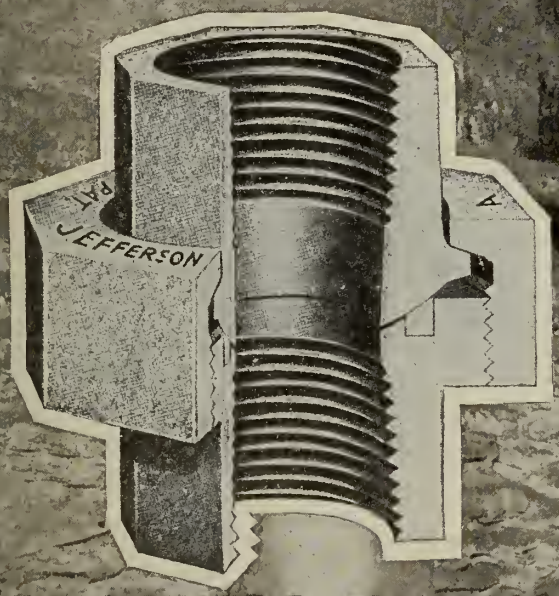
Insist on genuine JEFFERSON Unions—the name on the nut protects you from the "Just-as-good" variety.

Talk over unions with your jobber. He has JEFFERSONS in stock and can tell you why JEFFERSONS always make good.

Write for our catalog "UNIONS"

Jefferson Union Co.

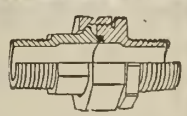
Lexington, Mass.



"LOOK FOR THE NAME ON THE NUT"

Male and Female Union. Takes the place of an all-female union and a nipple. Makes a short connection.

Union Elbow, all female. Takes the place of a straight union, nipple and an elbow. Also made male and female.



All Male Union. Saves two pipe joints between two female threaded parts.

Sarco Co., Inc., New York, N.Y.
Watson & McDaniel Co., Philadelphia.

STEEL BARRELS
Smart-Turner Machine Co., Hamilton, Ont.
Wm. B. Scaife & Sons Co., Pittsburg, Pa.

STEEL DRUMS
Smart-Turner Machine Co., Hamilton, Ont.
Wm. B. Scaife & Sons Co., Pittsburg, Pa.
